In 1955, Aron publishes one of his most famous books: *The Opium of the Intellectuals* (Aron, 1955). Adopting a critical perspective, Aron denounces the myths on which intellectuals base their argumentation. "Aron's 'skeptical' assault on the myths of the left, the proletariat and the revolution, and his philosophical dissection of the 'idolatry of history,' are at the service of restoring political judgment to its rightful place as the guardian of the human world," writes Dan Mahoney (Aron, 2001). The book is an attack on French left wing intellectuals like Sartre, and their tentative to fusion existentialism with Nietzsche's philosophy in the service of a Marxist interpretation of political action, explains Harvey Mansfield (Aron, 2001, 1969b). Aron interprets the intellectual mobilization in search of an earthly paradise as a new religion. Intellectuals were in need of a new religion, one that would promise salvation and the certitude of future restoration of a just and equalitarian society. Intellectuals were therefore the modern society preachers appealing to the faith in historical necessity that would transform pessimism regarding social reality into optimism of a future liberation and emancipation of the exploited.

Aron's understanding of the conflictual nature of human societies made it impossible for him to believe in the quest of the "best regime." Oppositions such as liberty and efficacy, consensus and political direction point out to the value of civil and political diversity (Mahoney, 1992).

On War and International Relations

Between 1972 and 1980, Aron elaborated his masterpiece: *Penser la guerre: Clausewitz* (Aron, 1976: vol. 1, and 1984: vol. 2). In the same time he wrote a number of articles, conference papers, and occasional texts on the Prussian "strategist and patriot." As Pierre Hassner points out, Aron's central points are the Trinitarian definition of war (the reasoning of the political authority, the free activity of the chief general of war, and people's passions), the theoretical status of the absolute war, and the subordination of the primacy of the war of annihilation to the primacy of politics, that is achieving political goals through war (Aron, 1987). But Aron saw more in Clausewitz than a work to be understood and interpreted. He used Clausewitz to understand the complex situations of world diplomacy and political arena in the twentieth century. As political relations in Europe are an inheritance from the nineteenth century, the themes of equilibrium of powers between rival National States and alliances of States are preeminent in the Cold War era. Two new developments joined this heritage only to render Clausewitz's thought of great actuality. On one hand, in the era of thermonuclear dissuasion, the possibility of Clausewitz's absolute war became from pure concept a real possibility and his theory of limited conflicts a common practice. On the other hand, the fact that Lenin was a reader of Clausewitz's textbook on popular war, and the implication of civilians in guerilla actions in the chessboard of the East–West conflict for global geopolitical positioning, rendered the theoretical framework of the Prussian General indispensible. In the aftermath of

World War II, the weakening of Western colonial powers, the chain reaction of wars of independence all over the globe, and the Soviet military dogma that called for a planetary armed opposition to the expansion and domination of Western capitalism, render the unfinished chapter of Clausewitz's work on civilian armament and popular resistance particularly challenging. Furthermore, as Clausewitz suggested, National State's rationality and interest do not act alone. Sentiments and passions like national pride, popular hostility, and animosities are always at steak in major geopolitical events as army or diplomatic confrontations.

But the most important point in Clausewitz's analysis of the phenomenon of war is his call on individual judgment. Following Clausewitz, Aron accords a special interest in the analysis of personalities of individual actors, politicians, or military chiefs in command. It is them that are called to take action in an uncertain landscape. Aron sees in the paradigm of war the very expression of conflictual situations implicating theoretical knowledge, trained action, and decision making. As Hassner (Aron, 1987) points out, the special relation between Aron and Clausewitz lies in the status they accord to the theoretical analyses of world history and historical events: they are not there to give us a doctrinal view of world's history or a system of scientific propositions that can be applied in every circumstance, functioning as prophecies by making right predictions; they only educate and train the glance and the judgment and thus help us make the right decisions or call the best historical and sociological judgments in the battlefield of world history, not only as chiefs of war or social scientists but also as plain observers and citizens. And this is Aron's greatest legacy.

Dealing with the international diplomacy and the indetermination of strategic relations, Aron interrogates the future of the European idea in the context of the planetary era. He analyses the conditions of possibility for a European cooperation and union rather than the 'dream' of an autonomous and united European power. He argues that, first, Europe is only a branch of a larger defense coalition, and, second, that one cannot create fatherlands (*patries*) on command. One should not count on the hate of Nations and the faith in international entities to promote the European ideal, but instead work on creating more dense cooperation and collaboration channels between the European Nations (Launay, 1995).

EDITOR IN CHIEF BIOGRAPHY

James D. Wright received his bachelor's degree in philosophy from Purdue University in 1969, a master's degree in sociology from the University of Wisconsin in 1970, and his PhD in sociology from Wisconsin in 1973. His first academic appointment was at the University of Massachusetts, Amherst, where he was promoted to Associate Professor in 1976 and to Full Professor in 1979. Most of his 15 years at Massachusetts were spent as Director, Associate Director, or Director of Research in the Social and Demographic Institute.

Wright left Massachusetts for Tulane University in New Orleans in 1988 where he served as the Charles and Leo Favrot Professor of Human Relations in Tulane's Department of Sociology. He also enjoyed a courtesy appointment in the Tulane School of Public Health, Department of Biostatistics and Epidemiology. He left Tulane in 2001 to become the Provost's Distinguished Research Professor of Sociology at the University of Central Florida. In 2003, he was named as the Director of the University's Institute for Social and Behavioral Sciences and in 2013, was designated as a UCF Pegasus Professor, the University's highest faculty honor.

Wright was the Editor in Chief of the scholarly journal *Social Science Research* from 1978 until 2014. His previous editing experience also includes a 20-year stint as editor of the Aldine de Gruyter book series *Social Institutions and Social Change*, two editions of the *Handbook of Survey Research* (Academic Press, 1983; Emerald Publishing, 2010), and service on the editorial boards of numerous journals. He is the author of 21 books and scholarly monographs on topics ranging from homelessness to research methods to NASCAR, and he has published more than 300 journal articles, book chapters, reviews, essays, and polemics. Wright lives with his wife Christine Stewart and their multiple dogs and cats in Winter Springs, Florida, where in his spare time he likes to cook fancy meals for large crowds.

PREFACE TO THE FIRST EDITION

Large and ambitious works such as the present Encyclopedia depend on countless instances of input, cooperation, and contextual support. Therefore, the editors in chief would like to express their gratitude to several institutions and individuals. Our most general thanks go to our respective home institutions, the Center for Advanced Study in the Behavioral Sciences, Stanford, and the Max Planck Institute for Human Development, Berlin. We are certain that without the effective infrastructures of these institutions and the rich collegial networks and intellectual climate they provide, implementing this Encyclopedia in such a short amount of time would not have been possible. In this context, we also need to mention that due to the administrative budgets provided to the editors in chief by the publisher, the financial strains on our home institutions were minimal. Such a situation may be a rarity in the modern world of scientific publishing where publishers often press scholars and institutions into taking on larger and larger shares of the publication enterprise.

Aside from the more than 4000 authors, our deepest thanks goes to the editors of the 39 sections, to whom we delegated many decisions at various stages, who were primarily responsible for developing the lists of articles and authors, and who stood as the main gatekeepers of scientific quality for the entries in their sections. As a group, the section editors displayed remarkable energy, intelligence, and tolerance for the inevitable frustrations of tending large numbers of authors over a long period of time. Because of the brevity of the acknowledgment of the main editorial coproducers here, we alert the reader to the list published as part of the front matter and the description of their extensive work we offer in the Introduction. We would also like to mention that one of our highly esteemed section editors, Franz Weinert, died unexpectedly during the last phases of his editorial work. For people who had the pleasure of knowing Franz Weinert, it comes as no surprise that he completed his editorial duties without ever complaining about the difficult health conditions he was facing. He was a gentleman and a distinguished scholar.

The International Advisors also gave wise counsel on several designated occasions, and a number of these scholars represented on the International Advisory Board took more initiative — always helpful — than we had originally asked. The International Advisory Board was particularly helpful in the process of choosing section editors. Some of its members assisted us ably as we attempted to make the Encyclopedia as international as possible and also in dealing with special problems that are part of a large project with close timelines. Thus, we remember a few occasions where members of the International Advisory Board helped us with their substantive and social competence to deal with matters of editorial disagreements. Because of the overall quality, collaborative spirit, and professional responsibility of our section editors, these events were rare indeed, but dealing with them required masterful and accelerated input. We appreciate the collegiality that members of the Board displayed when called upon in these special circumstances.

In addition, and as described in the Introduction, there was a host of esteemed colleagues who gave us advice on numerous questions such as author and editor selection, organizational matters, topics for entries, content and quality of selected articles, substantive and methodological niches to be covered, as well as last-minute author replacements. The number of such individuals is large indeed, and most likely, significantly larger than the list presented below. There were too many short, but nevertheless significant collaborative encounters that we likely did not deposit into our long-term memory or written documentation. We apologize for such oversights.

In this spirit, we appreciate the advice given in the three planning meetings in Stanford, Uppsala, and Dölln/Berlin by the following scholars: Peter Behrens, Burton Clark, Gordon Clark, Lorraine Daston, Meinolf Dierkes, Jean-Emile Gombert, Torsten Husén, Gérard Jorland, Ali Kazancigil, Wolfgang Klein, Gardner Lindzey, Renate

Mayntz, Andrew Pettigrew, Denis Phillips, Marc Richelle, Ursula M. Staudinger, Piotr Sztompka, Eskil Wadensjö, Björn Wittrock, and Robert Zajonc.

We would like to extend special thanks to Laura Stoker, who pinch-hit for Nelson Polsby (section editor for Political Science) who was unable to attend the meeting of section editors in April 1998; and to Linda Woodhead, Senior Lecturer in Religious Studies, Lancaster University, who assisted David Martin with editorial work at all phases for the section on Religious Studies.

We also acknowledge the help of scholars who advised Smelser and Baltes at the stage of pulling together the entry lists, proposing authors, and occasionally reviewing the content and quality of articles submitted.

Smelser thanks: Jeffrey Banks, Peter Bickel, Edgar Borgatta, Charles Camic, Jennifer Chatman, Jean Cohen, Michael Dear, Pierre Ducrey, Eckart Ehlers, Sylvie Faucheux, Steven Guteman, Frank Furstenberg, Helga Haftendorn, Peter Katzenstein, David Laibson, Stephan Lauritzen, Douglas McAdam, Eleanor Maccoby, Phyllis Mack, Cora Marrett, Douglas Massey, Donald Melnick, Harvey Molotch, Lincoln Moses, James Peacock, Trond Petersen, Andrew Pettigrew, Alejandro Portes, Matilda Riley, István Rév, John Roberts, Dorothy Ross, Rob Sampson, Fritz Scharpf, Melvin Seeman, James Short, Fritz Stern, Carol Swain, Ann Swidler, Ken'ichi Tominaga, Charles Tilly, Wolfgang van den Daele, Sidney Verba, Margaret Weir, Thomas Weisner, and Jennifer Wolch.

Baltes is very grateful to: Nancy Andreasen, Gerhard Arminger, André-Jean Arnaud, Jens Asendorpf, Jan Assmann, Margret Baltes (deceased), Jürgen Baumert, Peter Behrens, Manfred Bierwisch, Niels Birbaumer, Peter Bloßfeld, Walter Borman, Robert F. Boruch, Mark Bouton, Michael Bratmann, David Buss, Shelley Chaiken, Lorraine Daston, Juan Delius, Marvin Dunnette, Georg Elwert, Helmut Fend, Hans Fischer, Peter Frensch, Alexandra M. Freund, Dieter Frey, Jochen Frowein, Gerd Gigerenzer, Snait Gissis, Peter Gollwitzer, Ian G. Gotlib, David Gyori, Heinz Häfner, Helga Haftendorn, Giyoo Hatano, Adrienne Héritier, Theo Herrmann, Otfried Höffe, Ludger Honnefelder, Paul Hoyningen-Huene, James Huang, Günther Kaiser, Heidi Keller, Martina Kessel, Gábor Klaniczay, Wolf-Hagen Krauth, Achim Leschinsky, Karen Li, Shu-Chen Li, Ulman Lindenberger, Elizabeth Loftus, Gerd Lüer, Ingrid Lunt, Hans J. Markowitsch, Laura Martignon, Randolf Menzel, Dietmar Mieth, Susan Mineka, Setsuo Miyazawa, John R. Nesselroade, Claus Offe, Vimla Patel, Meinrad Perrez, Rosa Lynn Pinkus, Robert Plomin, Neville Postlethwaite, Thomas Rentsch, István Rév, Peter Roeder, Richard Rorty, Hubert Rottleuthner, Peter Schäfer, Heinz Schuler, Norbert Schwarz, Richard J. Shavelson, Joan E. Sieber, Burton Singer, Wolf Singer, Edward Smith, Hans Spada, Günter Spur, Rolf Steyer, Michael Stolleis, José Juan Toharia, LeRoy B. Walters, Elke U. Weber, Peter Weingart, and Reiner Wimmer.

There was one more group that played a special role in the editorial review (see also Introduction). Baltes was assisted by a team of colleagues who provided expert input to the section editors and to him during final review: Gregor Bachmann, Alexandra M. Freund, Judith Glück, Wolfgang Klein, Olaf Köller, Shu-Chen Li, Ulman Lindenberger, Ursula M. Staudinger, and Christine Windbichler. Their expertise in helping us to ensure quality is gratefully acknowledged.

The day-to-day organizational work of the editors in chief occurred at their respective research centers — the Center for Advanced Study in the Behavioral Sciences and the Max Planck Institute for Human Development in Berlin. Smelser singles out Julie Schumacher, his main assistant in the project, for her organization of the meeting of section editors, and her superb coordination of the flow of correspondence and manuscripts over several years. She remained firm when the rest of us were faltering, and displayed the greatest efficiency, intelligence, and good cheer. Smelser also relied on periodic help from Leslie Lindzey, Kathleen Much, Jane Kolmodin, and Anne Carpinetti. Michelle Williams of the University of California, Berkeley, served as his main editorial assistant for nearly 2 years, going over all entry manuscripts from the standpoint of readability, and carrying a great part of the cross-referencing work; her judgment was always the best, and Smelser is forever indebted to her.

At the Max Planck Institute for Human Development, and aside from Julia Delius (see below), Baltes expresses his deeply felt thanks to the main secretarial staff in his office (Helga Kaiser, Romy Schlüter, Conor Toomey) who during the preparation of this Encyclopedia took on larger shares of responsibilities for other projects and occasionally helped out when the editorial office was overloaded. More directly involved in the day-to-day operation of the Encyclopedia was Penny Motley, who efficiently functioned as project secretary during the planning phase. During the main phases of the project, it was Yvonne Bennett who was responsible for secretarial and organizational matters. She deserves much applause for her superb and efficient help in the day-to-day running of the editorial office, making sure that all manuscripts and proofs were processed quickly, and also for assisting with the organization of various meetings. Not least, Baltes thanks the administrative office of the Max Planck Institute, and there especially Nina Körner and Karin Marschlich, for their competent work in managing the project budget, as well as Sabine Norfolk who handled most of the numerous fax

transmissions with ever present smiles and friendliness. Finally, in the Berlin editorial office, thanks are also due to Susannah Goss for her excellent work in translating individual articles into English.

Individual section editors wish to thank the following scholars who gave them substantive advice in their work: Richard Abel, Itty Abraham, John Ambler, Karen Anderson, Mitchell Ash, Alan Baddeley, Boris Baltes, Manfred Bierwisch, Michael Bittman, Sophie Bowlby, John Carson, Shelly Chaiken, Roger Chartier, François Chazel, Stewart Clegg, Carol Colby, Philip Converse, James Curran, Jerry Davis, Natalie Z. Davis, Peter Dear, Juan Delius, Michael Dennis, Josh DeWind, Sherry Diamond, Elsa Dixler, Georg Elwert, Howard Erlanger, Drew Faust, Malcolm Feeley, Nancy Folbre, Michael Frese, Angela Friederici, Lawrence Friedman, Bryant Garth; Victor Ginsburgh; Marcial Godoy, Frances Goldscheider, Calvin Goldscheider, John H. Goldthorpe, Reginald Golledge, William Graziano, Stephen Gudeman, Mauro Guillen, Doug Guthrie, John Hagan, Eric Hershberg, Steve Heydemann, Stephen Hilgartner, Judith Howard, William Howell, Jill Jaeger, Bob Kagan, Joe Karaganis, Roger E. Kasperson, Ronald Kassimir, Robert W. Kates, Wolfgang Klein, Hans-Dieter Klingemann, Bert Kritzer, Kay Levine, Steven Lukes, Michael Lynch, Akin Mabogunje, Stuart Macaulay, Donald MacKenzie, David Magnusson, Michael McCann, Sally Merry, Peter Meusburger, Sieglinde Modell, John Monahan, Kevin Moore, Gerda Neyer, Hiroyuki Ninomiya, Jodi O'Brien, Eva Oesterberg, Mark Osiel, James L. Peacock, Susan Phillips, Trevor Pinch, Wolfgang Prinz, Sheri Ranis, Harry Reis, Estevao C. de Rezende Martins, Marc Richelle, Leila Rupp, Gigi Santow, Austin Sarat, Simon Schaffer, Linda Scott, Tim Shallice, Seteney Shami, Ronen Shamir, Susan Silbey, Wolf Singer, Sheila Slaughter, Gerhard Strube, Ursula M. Staudinger, J. Stengers, Stephen M. Stigler, Michael Stolleis, Mark Suchman, Denis Szabo, Verta Taylor, Ashley Timmer, David Trubek, Leslie Ungerleider, Don Van Arsdol, Jakob Vogel, Rita Vörg, Judy Wajcman, Mary Wegner, Wlodzimierz Wesolowski, Steve Wheatley, Björn Wittrock, and Vincent Wright (deceased).

Section editors also thanked the following persons for their research assistance: Pamela Anderson, Susan Augir, Anja Berkes, Chantale Bousquet, Aida Bilalbegović, John Clark, Susanne Dengler, Kathrine Derbyshire, Annie Devinant, Casey B.K. Dominguez, Barbara Dorney, Elizabeth Dowling, Tracey L. Dowdeswell, Carolyn Dymond, Debbie Fitch, Susannah Goss, Verhan Henderson, Andrew Hostetler, Gudrun Klein, Heike Kubisch, Angie Lam, Ellen Lee, Valerie Lenhart, Kay Levine, Allison Lynn, Helena Maravilla, Carol B. Marley, Marion Maruschak, Michael McClelland, Rhonda Moats, Birgit Möller, Katja Neumann, Linda Peterson, Justin Powell, Paul Price, Xandra Rarden, Chris Reiter, Deborah Sadowski, Heidi Schulze, Heidi Sestrich, Keith Smith, Judith Thompson, Karen Varilla, Stuart Vizard, Danelle Winship.

It is difficult to single out one person as especially helpful. Despite the risks involved, we would like to highlight one person (see also Introduction). As shown in the front matter, beginning in the second year of the planning phase, Julia Delius served as our scientific editorial assistant. For our internal process of editorial review and management, Julia Delius was the mastermind of editorial coordination. Her work was simply outstanding.

Finally, we express our thanks to several individuals at Elsevier publishers whose work was both essential and helpful to us throughout. Barbara Barrett started the ball rolling for the entire Encyclopedia project, and was a master at negotiating out the fundamental arrangements at the beginning. Geraldine Billingham, as executive editor, also played an important role in the development of the project, as well as carrying the heavy responsibility for ensuring that all the financial and operational aspects of the project were realized. She executed this work with directness, skill, and tact. Angela Greenwell coordinated the editorial process with dexterity, calmness, and good judgment. Three persons were responsible for monitoring the progress of entries from Elsevier's side: Michael Lax for a time at the beginning; Jayne Harrison, who carried an overwhelming load of manuscripts month after month, and Helen Collins, who was responsible for the equally demanding job of shepherding the manuscripts through the entire production process. Ruth Glynn skillfully and imaginatively masterminded the development of the electronic version within Science Direct. We know how much the success of the Encyclopedia has depended on these individuals and their staffs, and our appreciation and admiration is here recorded.

Our expressions of gratitude and respect for the authors, section editors, reviewers, counselors, and editorial team, however, are not meant to distract from our own responsibilities as editors in chief. Let us hasten to add, therefore, that those whom we acknowledge deserve most of the credit but little of the blame for whatever shortcomings remain.

INTRODUCTION

Alan Sica's article in this encyclopedia observes, "The urge to systematize and rationalize both common and esoteric knowledge has been strongly and continuously in evidence for at least 2400 years in the West" (Sica, 2015). Sica dates the origins of this urge to Plato's nephew Speusippus, who took up the challenge of Plato's call for an *encyclopedia* (from Greek words meaning 'general education'), and traces the urge though Pliny the Elder, Vincent of Beauvois, Francis Bacon, Denis Diderot, and a great many others. Today, an encyclopedia is simply a self-contained reference work "with two aims: to include up-to-date knowledge about a particular discipline or group of disciplines and to make this knowledge conveniently accessible" (Smelser and Baltes, 2001). Such are the aspirations of the present work.

Histories of the concept of an encyclopedia are widely available and need not occupy us here. Those interested in where the *International Encyclopedia of the Social and Behavioral Sciences* (IESBS) fits into the long history of encyclopedias will do well to consult the Sica article quoted above or the Smelser—Baltes 'Introduction' to the first edition of this work.

This is the second edition (2/e) of the IESBS. Elsewhere, I acknowledge my immense debt to the editors of the first edition, Dr Neil Smelser and Dr Paul Baltes. Without their perspective and template to follow in assembling the second edition, this version would have scarcely been possible. The very thought of an encyclopedia covering *all* the social and behavioral sciences, one that drew on scholars from *all* corners of the globe, is itself so audacious that one would hesitate even to begin without a pretty detailed road map to the terrain.

On the occasion of the publication of Robert E.L. Faris's widely acclaimed *Handbook of Modern Sociology*, Joseph Gittler was moved to ask, "With the plethora of new handbooks, reviews, and compendia in sociology, one wonders whether there is a need for yet another one." That question was posed almost 50 years ago; the ensuing half-century has been marked, as Sica says, by "an avalanche of reference materials the likes of which had never been seen in libraries prior to about 2000." So readers and critics are within their rights to ask: Why a second edition? Why now?

The first edition (1/e) was reviewed in *Contemporary Psychology* as "the largest corpus of knowledge about the social and behavioral sciences in existence" (Park, 2004). According to readily available data sources, IESBS 1/e has been cited nearly 6000 times in subsequent scholarly literature and has an h-index ($h = 24$) that would be the envy of many full professors. Citations are only one measure of impact, of course, and probably not the most important measure for a basic reference work intended more for students and a general audience than for practicing professionals. In addition to the thousands of scholarly citations, items from IESBS 1/e were 'hit' almost two *million* times on Science Direct between online publication in November 2002 and August 2014 — two million instances where IESBS 1/e was likely consulted as a basic reference source, to get quickly up to speed in a new area of research or to provide background for a paper or project, or just to satisfy a reader's curiosity. The first edition, in short, emerged soon after publication as a go-to reference work throughout the social and behavioral sciences. Michael Shanahan referred to the first edition as "the atomic bomb of reference works." It was thus an easy conclusion that the work had sufficient value to keep it alive and current.

In reading selected articles from the first edition, however, I was taken aback by how much and how quickly they had aged. The first articles I looked at were those pertinent to my own areas of research and in nearly every case, there was important recent work that I felt needed to be discussed. With the assistance of colleagues in other areas of the social and behavioral sciences, it became obvious that this was a general problem. To be sure, much of the material in 1/e has enduring value; indeed, roughly half the articles in 2/e are updated and revised items from the first edition. Still, it is sobering to realize just how quickly the frontiers of social science

knowledge shift and thus how quickly a basic reference source becomes dated. I am certain there are articles in the current edition that are already in need of some updating.

Smelser and Baltes enumerated six criteria that guided their decisions about what to include and what to leave out. The criteria are as follows:

1. secure knowledge, realizing that security of knowledge is a dynamic and relative term,
2. knowledge with balance and comprehensiveness,
3. knowledge that is integrative rather than fragmented,
4. knowledge that places the evidence into historical and theoretical context,
5. knowledge that highlights connections between topics and fields, and
6. knowledge that combines, where possible, theory and practice.

I would like to say I have followed these same criteria in determining the content of 2/e, but all six criteria have proved problematic in one or another way and thus deserve some comment in light of the present work:

1. What is secure knowledge today is apt to be recognized as wrong tomorrow. Many of our requests for updates to 1/e articles generated some response to the effect, "All of this is completely obsolete. We need to write a new entry from scratch." One would expect this to be true of areas of research such as behavioral genetics, say, or cognitive neuroscience or other fast-moving scientific fields, but it also turns out to be true of archaeology, history, and philosophy. The leading edge of research in *every* discipline threatens received wisdom; those who content themselves with received wisdom ('secure knowledge') will quickly find themselves behind the times. So our charge to authors was to focus less on the 'secure knowledge' in their respective fields and more on the cutting edge — the new perspectives, methods, findings, and issues that will animate social and behavioral science research in the coming decade.
2. Throughout the social sciences, the distinction between theory and ideology is sometimes difficult to discern, and so too the distinction between applied research and community or political activism. We need not invoke Max Weber's conclusions about the impossibility of a truly value-free social science to understand that ideological undertones and political preferences can often be detected in social science research work; sometimes, they are quite explicit. Nor is it much of a surprise to learn that many social scientists struggle, not always successfully, to distinguish between what they want the world to be and what the world in fact is. Such struggles are part of the process by which knowledge develops and are thus in evidence in many of the 2/e articles. It would be unwise to enforce by editorial fiat a consensus on issues that the social sciences themselves have yet to resolve.
3. The fragmentation of knowledge *across* disciplines is far more serious that the fragmentation of knowledge *within* them, although the latter is a problem as well. Many well-informed sociologists, for example, take pride in reading widely and can speak with some authority about what is going on in the field, even in areas of sociology that do not directly concern them. I assume this is also true of the other social and behavioral science disciplines and areas. But rare is the sociologist who is cognizant of work being done, say, in social geography *even when*, as is often the case, the fundamental problems, theoretical issues, and methodological approaches are similar. This is a widespread problem across the disciplines: The evolutionary psychologists do not know as much as they should about what the anthropologists are doing; the economists ignore a lot of pertinent work in sociology and political science; etc. For better or worse, disciplinary differentiation is an inherent element in the process of knowledge development and discovery, so this is a reality to be faced, not a problem to be solved. We dealt with this reality mainly in two ways: (1) Authors were encouraged wherever possible to think across rather than strictly within their disciplines. (2) Calling relevant work done in other disciplines to the reader's attention was a guiding principle for the choice of cross-references for each article.
4. Social-constructionist theories of knowledge would argue that knowledge does not become knowledge until it is placed in historical, cultural, social, political, and theoretical context. As put very simply and succinctly in the opening line of the famous text by Berger and Luckmann, "reality is socially constructed" (1966: 1). This is no less true of social science knowledge than knowledge in any other realm. Unfortunately, a great deal of what we think of as social science knowledge is based on biased samples of WEIRD people — that is, Western, Educated, Industrialized, Rich, and Democratic (Henrich et al., 2010). (The same point has, of course, been made by many others.) The WEIRD, thus defined, represent a rather exotic minority group judged by world standards, and the challenge for IESBS 2/e was therefore twofold: (1) to recruit non-WEIRD editors and authors where possible; and (2) to persuade all authors to incorporate comparative, cross-cultural, and

international themes and perspectives wherever it was possible to do so. This effort was more effective in some sections than in others. Moving away from nation-specific literature, themes, and results to a truly *international* (the I in IESBS) account of the social and behavioral sciences was an ever-present *desideratum* in my discussions with editors and authors.

Alas, an emphasis on cross-culturalism often brings to light that everything, or nearly everything, seems to vary by culture, subgroup, ethnicity or nation, and at that point the question arises whether social science generalization is even possible. Are there universals that cross all social groupings? Or does social science dissolve into a mist of group-specific particularities that adduce no general principles? That hardly seems desirable. Yet myopic and ethnocentric fixations on one's own society or culture are scarcely to be encouraged either.

The worst offenders in this regard tend to be social scientists from the USA (and from the West more generally), who, of course, also comprise the largest share of editors and authors for IESBS 2/e. True, as with greenhouse gases, the USA (and the West) also produce the largest share of the world's science, social and otherwise, and so it is inevitable that they also represent the largest share of IESBS 2/e contributors. The Swedish social anthropologist Ulf Hannerz wrote about this very issue in his marvelous essay, "Editing Anthropology" (Hannerz, 2010). Hannerz quotes a Canadian anthropologist who said of the "neighborly presence" of US anthropology that it was like being "in bed with the elephant." The same is true of most or all of the disciplines covered in this work. But then in a passage remarkable for both its insight and its generosity, Hannerz remarks, "No doubt tensions and conflicts may arise out of this situation, but perhaps it is better to understand that the elephant cannot help being an elephant, and that it makes sense for it, in its habitat, to behave in elephantine ways. A well-trained elephant, too, can do a lot of good, such as in carrying heavy loads." So if the elephant that is Western social and behavioral science has been pressed to carry the heavier load in these pages, that is, the price to be paid for being an elephant in the first place.

The larger issue here is that the social and behavioral sciences, which were largely birthed in the West, in Europe and the United States, mainly address a trans-Atlantic scientific dialogue, a dialogue that is carried out almost exclusively in English. Indeed, throughout much of the world, a scientist's stature is indexed in part by his or her success in publishing in English. Publications in the native language are simply *assumed* to be inferior. The main exceptions, tellingly, are French and German social scientists whose native-language publications are valorized. A Dutch or Portuguese or Hungarian social scientist who only published in the native language would be seriously punished in merit and tenure reviews. Elsevier's citation database Scopus *requires* English-language abstracts before a journal will even be considered for inclusion. And English (with American spellings) is likewise the official language of this encyclopedia. No resources were made available to get articles submitted in other languages translated (although several such articles were submitted). Inevitably, this biases the encyclopedia's coverage in favor of social science addressed to the trans-Atlantic dialogue. Consequently, a great deal of excellent social science published in Spanish, or Mandarin, or Farsi, or any of the other world languages, is overlooked.

That said, steps were taken to improve the internationalism of the encyclopedia's coverage throughout the 4 years of its development. To begin, I sought area and section editors from around the globe and urged them whenever possible to seek international (vs strictly Western) authors. Articles were often returned to their authors with explicit instructions to add international coverage. And when all efforts failed and we ended up with articles that were unmistakably restricted to a single nation in their coverage (frequently but not always, this was the US), I indicated the national focus in the article subtitle. Still, a great deal more WEIRD social and behavioral science remains in these pages than would be desirable in an *international* encyclopedia. In a later section, I give the national breakdown of everyone involved in this project.

5. An encyclopedia that "highlights connections between topics and fields" is easier to envision than to accomplish. Criterion (3) above speaks to the disciplinary fragmentation of our social science knowledge. William Easterly, the NYU economist, has written about the 'tyranny of experts' but the tyranny of the disciplines is an equal problem, a tyranny sanctified by the very academic structure of the modern university, where the separate and often warring colleges are each comprised of assorted departments, the latter representing basic academic disciplines. Interdisciplinary programs are almost invariably relegated to various centers, institutes, or specialized research laboratories — in short, to the periphery of the university's power structure. And while everyone *says* they want to encourage multi- and interdisciplinarity, very little is done to make that happen. Instead, departments remain as the fundamental unit of academic organization.

   Hortatory admonitions to editors and authors have made IESBS 2/e somewhat more interdisciplinary than its several predecessors, but in the end, the disciplinary emphasis in many of our articles would be hard

to overlook. Still, there are many sections of the work that were clearly developed with interdisciplinarity in mind and in which one finds interdisciplinary social science at its current best: environmental and ecological sciences; health; life course; sexuality; GLBT studies; public policy; evolutionary sciences; war, peace, violence, and conflict; and genetics, behavior, history, and society are a few sections that come immediately to mind.

I am particularly pleased with the extensive coverage given in 2/e to the interactions between the biological and social sciences. Harry Whitaker once remarked in a private e-mail that "we are all witnesses to the marriage of biology and the social sciences." Many of the articles found here are offspring of that marriage. And those articles leave little doubt that the future offspring of this marriage will be among the most exciting and insightful social science products of the coming decade.

The social sciences once resisted everything biological as rank reductionism; in addition, the social scientists have always feared that a mature and complete biology would eventually drive us out of business. Articles included in IESBS 2/e make it clear that 'nature' versus 'nurture' was the wrong question from the very beginning, that what we need to understand is how biological inheritance and social and cultural forces *interact* to produce individual and collective outcomes. This is where a lot of the interesting action in the social sciences is going to be in the coming years.

6. The coverage of the practical or applied sides of the various disciplines has been increased in this edition, so the applied content of 2/e certainly exceeds that of its predecessor. New to this edition is the entire section on applied social and behavioral sciences; also new is our large section on social work and the separate section on applied, industrial and organizational psychology. But as Sara Strickhouser and I say in our article on the history of applied social research, "The history of 'applied social science' is indeed the history of the social sciences themselves" (Strickhouser and Wright, 2015). All of the social sciences in their modern form were birthed in the post-Enlightenment effort to understand why people, their institutions and society as a whole were as they were — why greed was more visible than generosity, why oppression was more common than freedom, why inequalities of various sorts characterized every social institution. To the founders of the disciplines, the modern distinction between basic and applied scientific concerns would have seemed meaningless, as indeed it was.

The Planning Phase and Editorial Structure

Elsevier's original acquisitions editor for this project, Scott Bentley, discussed the broad outlines of our attack on IESBS 2/e with me in a series of phone calls in the early months of 2010. By May 2010, certain of these outlines had come into sharp relief. There would be a single editor in chief with a tier of 'responsible lieutenants' to assist. These lieutenants started out as advisory editors but soon morphed into the 10 area editors in the final editorial structure. Each area editor would in turn oversee various sections and each section would have its own editor or editors. The original plan was that the area editors would each be responsible for approximately 400 articles and each section editor responsible for about 100 articles, so that no one would have an excessive amount of work compared to everyone else. In the end, however, some sections required more articles and others fewer, so the areas vary from fewer than 300 to more than 600 articles, and the sections vary from fewer than 30 articles to well more than 200.

Prior to my first discussions with Scott Bentley, Elsevier had commissioned about 20 'market surveys,' roughly half from professional librarians and the other half from academics, each focused on 'what was right and what was wrong' with the first edition. The most insistent demand that surfaced was for a fully electronic, computer-searchable work either in addition to or instead of a print version. In the end, both an e-version and a print version are being made available. But there were also consistent concerns expressed about spotty coverage of some areas: no coverage of social work to speak of; inadequate coverage of accounting, marketing, and business; no separate section of criminology; haphazard coverage of applied topics and concerns; and so on. And there were the predictable concerns about undue Western domination of the work.

Working from the 1/e Table of Contents and this stack of 20 surveys, I tinkered for a few months with how best to expand coverage to address the concerns our reviewers had expressed; the result was (more or less) the editorial structure shown elsewhere in the front matter of this work. Thus, the 53 sections of 2/e are basically the 39 sections of the first edition plus sections that were added to cover important emerging areas of research interest (e.g., gay, lesbian, bisexual, and transsexual studies) or to provide deeper coverage of disciplines and subdisciplines that the first edition treated lightly if at all (applied social and behavioral sciences, social work). A

few of the first edition sections were eliminated entirely: specifically, integrative concepts and issues (something of a catch-all category for 1/e articles that were highly interdisciplinary or simply did not fit anywhere else) and gender studies (gender is now so thoroughly integrated into the research and thinking of all the social and behavioral science disciplines and subdisciplines that a separate section was unnecessary and somewhat retrograde). Others were altered or expanded in significant ways (organizational and management studies, for example, became the second edition section on management, organizations, business, marketing and finance; expressive forms evolved into the 2/e section on culture and the arts; linguistics was subdivided into three separate sections; etc.) And some subdisciplinary areas that were part of other sections in the first edition were given their own sections in the second (life course studies; sexuality; criminology; labor studies; and war, peace, violence, and conflict are the most prominent examples), just to ensure adequate coverage.

The Introduction to 1/e (Smelser and Baltes, 2001) discusses at great length the intellectual architecture of the first edition and its evolution; the agonizing decisions about rules for the biographical articles; whether to organize the work by discipline, by concept, by an a priori taxonomy of social science knowledge, or in some other manner; and related structural matters. What resulted in 1/e was something of a hybrid model with some sections clearly representing specific disciplines, others representing 'overarching topics,' still others representing 'intersecting fields,' and so on. My task was far less challenging: I thought the architecture of the first edition served its purposes admirably and so I adopted it wholesale for the second edition, with the small modifications noted above.

While each of the 53 sections of 2/e has some more or less obvious justifying logic or substantive or disciplinary coherence, their arrangement into the 10 areas of the second edition does not. As already indicated, decisions about what sections to include and exclude were made very early in the development of the second edition, based on what was in the first edition, what Elsevier's marketing surveys suggested as significant lacunae, and my own sense of things. The arrangement of the sections into areas came later and was dictated largely by the interests and expertise of those who had been persuaded to sign onto the enterprise. Thus, all the Linguistics sections are in Area Five along with the cognitive and neuroscience sections because Harry Whitaker at Northern Michigan University had been a linguist first, a neuroscientist second, and a historian of psychology third. Likewise, Area Eight contains its seemingly chaotic hodgepodge of evolutionary sciences, genetics, religious studies, science and technology studies, and law because these happen to be the fields of interest of the redoubtable Barbara Prainsack of King's College, London, whose editorial talents are as deep as her interests are broad. Simplifying only slightly, section editors were chosen for their substantive expertise in particular areas of research (as well as their international or cultural 'range'); the plan was that section editors would review each of their articles for completeness of coverage, currency, fairness, and the like. In contrast, area editors were chosen for their breadth of interest and knowledge spanning multiple sections – people who by nature, experience, and training would be good at seeing the big picture. The role of the area editors was to assure that the articles were at least modestly international and interdisciplinary and formed some sort of coherent whole.

As laid out in an early e-mail to one of the area editors, "In my mind, Advisory [Area] Editors are generalists and Section Editors are content specialists. The Section Editors need to bring breadth of knowledge to their responsibilities, of course, but the primary job requirement is expert understanding of the particular field or section. We need section editors who can commission pieces that adequately review past developments in the subject area, but who can also shape their portfolios to identify major unanswered questions and new research developments." This was the general model followed throughout the recruitment process.

The approach just sketched inevitably left a residual area made of up sections that none of the other area editors were willing or able to claim. That proved to be Area Ten. A very large number of scholars from various disciplines and world regions were approached about serving as the Area Ten Editor. All demurred until I approached Martin Bulmer of the University of Surrey, who served the project for about a year but was unable to continue and subsequently left the Board. So for the final year of the project, the editing of Area Ten was done mainly by me.

The online subject classification for IESBS 1/e did not correspond precisely to the sections of the first edition; the subject classifications listed articles by broad general topic regardless of which 1/e section developed them. So for the first year or so, my assistants and I labored to assign every 1/e topic to one of the 53 2/e sections. With 53 sections to populate with articles and about 4000 articles to classify, the process of assigning articles to unique sections occupied huge amounts of time and generated endlessly complicated spreadsheets. (After about a year of this, a document surfaced in the Elsevier archives that showed exactly where each 1/e article had originated.)

Along with populating the 2/e sections with articles, searching for area and section editors occupied a major part of the early going. The original idea was to identify the 10 area editors first and then enlist them in the

search for their section editors, but in fact, these processes were simultaneous and were about half-completed when the two planning meetings were held: the first in San Diego on 19 and 20 May 2011; the second in London on 5–7 June 2011. Although not part of the plan, the first meeting was mostly attended by area editors and the second, by section editors.

The agenda for both meetings was largely identical: achieve clarity on the respective roles of the various editors; solicit advice on filling the unfilled editorial slots; get buy-in on the project *mantra* (internationalism, interdisciplinarity, inclusiveness!); explain the relationship between the first and second editions (e.g., that all 1/e authors would be offered the opportunity to update their articles); explain the process of assigning articles to sections; and the like. In almost all cases, consensus was quickly forthcoming.

The largest substantive change in the second edition is the treatment of psychology. (Whether measured by students, practitioners, professors or programs, psychology is the largest of the social and behavioral sciences.) In the first edition, the whole of psychology was contained within four large sections: clinical and applied psychology; developmental, social, personality, and motivational psychology; cognitive psychology and cognitive science; and behavioral and cognitive neuroscience. Cognitive science and neuroscience are, of course, rapidly growing sectors of the psychological discipline and it seemed appropriate to devote an entire area of the second edition to them. This area contained seven separate sections (three of them devoted to linguistics). And the 'softer' psychological sciences were placed in a separate area comprised of eight sections (including psychiatry and social work). These changes were made to assure that 2/e had adequate coverage of the entire psychological enterprise (a concern that was raised in some of the reviews of 1/e).

The structure of the editorial team was developed to serve two purposes: first, to divide up the labor into manageable parts; and secondly, to assure that every article in the final product would be reviewed by at least three scholars: the respective section editor, area editor, and the editor in chief. Since we were all aware of one another's identities throughout, the review process was not blinded, but every article in this work has been thoroughly peer-reviewed and vetted. In many cases, these articles have been through four, five, six, or even more revisions before being accepted for inclusion in the work.

Recruiting Editors and Authors

IESBS 2/e faced two different recruiting tasks: recruiting editors and recruiting authors. As indicated elsewhere, the original plan was that I would recruit area editors largely from my own personal networks and they in turn would recruit their section editors. In practice, the process was much more convoluted. First off, many of my 'first choice' candidates were hesitant to involve themselves in such a daunting and ambitious project. In some cases, an initial agreement to come aboard was followed a few weeks or months later by withdrawal as the true scope of work came into sharper focus. Some people that I tried to recruit as area editors demurred but agreed to serve as section editors; in other cases, candidates for area editors were nominated by section editors. In a couple of cases, there was a complete team of section editors prior to the successful recruitment of a corresponding area editor. And so on. The process of assembling an editorial team for the project was by no means linear.

Personal networks – mine and those of the people I persuaded to sign on – were the largest single source of ideas for other editors, by far. But personal networks tend to follow disciplinary and national lines and become rather quickly exhausted. In selecting both editors and authors, it was of course essential that all relevant perspectives be covered and that the breadth of fields was adequately represented. So other sources of ideas were tapped: the expertise of the Major Reference Works team at Elsevier; editorial boards of leading journals in the respective fields; Google Scholar citation counts; the knowledge and networks of people who had been involved in preparing the first edition – basically, anywhere names of top scholars in particular areas could be located. I did not keep systematic track of the number of people approached, much less of the outcomes; but in reviewing my e-mail archives from the early period of the project, I probably asked (on average) somewhere between six and eight prospects before I found someone to agree (an average that was highly variable across the areas and sections).

In the initial plan, area editors would recruit their own section editors and the section editors would in turn recruit their own authors, but the reality was again different. Inevitably, my negotiations with prospective editors (both types) would often result in a declination of the editorial role but an offer to write an article on a particular topic (or topics), offers I readily accepted. So in some cases, I had committed authors of particular articles well before I had the corresponding section or area editor in place. And many of the section editors likewise leaned on their area editors and on me for author suggestions, contacts, and outreach. So all the editors

were involved in locating willing authors (and not coincidentally, in making suggestions for articles to be included in the final work).

No one was asked to keep precise statistics on how many authors were sought before an agreeable author was found. My sense is that the 2/e editors had a somewhat tougher time with this than the 1/e editors had (but on the other hand, the 2/e editors had all the 1/e authors to work with, which Smelser and Baltes certainly did not have). The 1/e editors report that about 60% of those invited to write articles agreed to do so on the first 'ask' (with equivalent success rates in each subsequent 'ask'). In 2/e (or so I would guess), the success rate was probably closer to 50% and possibly even lower. They also report that something in excess of 90% of those who agreed to write for 1/e in fact contributed "acceptable entries in time to be included…" In the 2/e case, we found ourselves still soliciting authors within a few weeks of the submission deadline and some dozens of authors pulled out of the project at the last minute. Still, when all the dust settled, there were just about 800 articles planned for both editions that never materialized and both editions ended up with just fewer than 4000 articles. Perhaps these are 'natural limits' for a work of this sort.

Biographies*

In the Introduction to 1/e, Smelser and Baltes provided a short history of and rationale for the decision to include a limited number of biographical articles (150 of them, to be exact). This was evidently a controversial and contested decision since some of those associated with 1/e felt that biographical articles had no place in an encyclopedia focused on substantive knowledge (versus the personalities of those who produced it). As Newton said (paraphrasing a passage from Bernard of Chartres), "If I have seen further, it is by standing on the shoulders of giants" (a passage made famous among social scientists by Robert K. Merton's *On the Shoulders of Giants* (1965)). In other words, discovery is only possible because its discoverer is able to refer to knowledge already gathered and accumulated by his or her predecessors; and since all discoveries – small and large, substantial and minor – contribute to the production and accumulation of knowledge, singling out particular scholars for special attention would be both pointless and invidious.

This position, although understandable, was abandoned in the first edition and remains so in the second, largely because it is not possible to understand the social sciences without knowing the individuals who contributed to it. C. Wright Mills once defined the sociological imagination as the intersection of biography and history (Mills, 1959). To know the social sciences therefore requires biographical and historical knowledge. The social sciences are distinguished from the physical and biological sciences in the way they produce knowledge because individual human beings, including social scientists, invest meaning in their actions. Only through understanding the meaning that individuals give to their actions are social scientists able to provide explanations of human behavior and its outcomes. And what applies to social action in general applies to the production of social science knowledge as well. It thus makes sense to include biographical accounts of social science personages who have been particularly distinguished in making sense of human action and have in turn made major contributions to social science knowledge. To acknowledge individual social scientists with biographical articles is also to acknowledge their special and particular insights.

Once the decision was made to include biographies in 1/e, the next major decision was whom to include and whom to leave out. Two arbitrary but defensible principles governed these decisions: (1) the total number of biographies was not to exceed 150 (chosen because it seemed like a manageable number) and (2) only biographies of the dead would be included. The 1/e section editor for biographies, Karl Ulrich Mayer, consulted handbooks and encyclopedias, asked other section editors to name and rank the most important names in their respective disciplines, ran citation checks, and finally submitted a consolidated list to various experts for review. This resulted in some additions and some deletions and in the end 147 biographies made it into the first edition.

Instructions to authors writing these biographies directed them to include "a brief sketch of the major dates and events in the life of the biographee," to describe "the major contours of the [person's] substantive contribution," and to highlight the "importance and relevance of the biographee's work for the social and behavioral sciences." Largely the same instructions were given to 2/e biographers.

The selection criteria for 2/e were very different. First, on the reasoning that well-done biographies of leading figures is one of the things that draw readers to a work such as this, the total number of biographies was

* My thanks to Andreas Hess for drafting this section of the Introduction.

increased by more than 100 (to just over 250). In a major departure from 1/e, much of the increase is made up of biographies of the living. The 1/e restriction that excluded living persons resulted in anomalies that we thought needed to be addressed. As life expectancy has expanded in the twentieth and twenty-first centuries, so have the life spans of social scientists. Claude Levi-Strauss, to cite one obvious example, lived to the age of 101 years. When 1/e was published, he was in his 90s, was widely cited, was recognized universally as a modern classic, indeed a genius, of social anthropology – and yet, owing simply to his longevity, he was not included in the 1/e biographies. Biographies of, for example, the economist Herbert Simon, the political economist Albert O. Hirschman, the sociologist and philosopher Jürgen Habermas, and the linguist Noam Chomsky were all excluded for the same reason; indeed, Habermas and Chomsky still live as this is being written (Fall, 2014). In all these cases, the major works had been produced decades earlier, their major imprints on the social and behavioral sciences were already evident, their eventual inclusion in works such as this was inevitable. Are readers to be deprived of accounts of their lives, times, and contributions just because they have survived into deep old age?

Once the decision was made to include biographies of the living, however, it was not always easy to decide who among the living merited inclusion. Often the editors had to make decisions on a case-by-case basis, frequently in extended consultation with colleagues or experts in the field. Criteria used to make these decisions were whether the potential biographee had a reputation beyond one culture, nation, or language group; whether there was a record of sustained production over several decades; and whether there was an impact beyond the confines of a single discipline. These criteria reduced our list of suggested biographees considerably. Early lists of candidates numbered as many as 200 new names (in addition to the 147 biographies included in 1/e). In the end, as noted earlier, somewhat more than 100 new names were added.

In a few cases, persons were included that arguably did not satisfy our inclusion criteria. One such is Raul Hilberg, who became famous mainly for having written one very important book, *The Destruction of the European Jews* (1961). Hilberg's book is still regarded as the seminal work in Holocaust studies, a field of research that came to prominence much later; we felt that his signal contributions to Holocaust studies merited a biographical article. Much the same could be said, perhaps, of André Gorz, a well-known social theorist from France, and Albert Memmi, whose work is on colonialism, anticolonialism, and racism. These and other examples could and probably will raise questions about the porousness of our criteria. Whether we were right in giving 'trespassers' their space is open to debate. In any case, whether Hilberg, Gorz, Memmi, and others do or do not merit their biographies is for readers, not us, to decide.

Other important changes in the 2/e biographies section include, first, a conscious effort to attain a better gender balance, including more women both as biographees and as authors; and second, expanding the biographies both geographically and culturally. In the end we made some inroads in both respects but fell short of our internal goals. One of the main reasons for this is that any encyclopedia must, in the first instance, be true to the disciplines it represents. This means being true to the real status of important players, their networks and disciplinary power relations, and their academic capital in their respective fields and beyond. Change in these respects has been noticeable; certainly, the growth of the social sciences in Asia has been remarkable; and in most disciplines, the proportional presence of women has increased. But modest change in the right direction does not a revolution make. Too many nonwhite, non-Western, and nonmale practitioners are still being left out on the disciplinary peripheries and are not fully represented – not in their home disciplines and not in our encyclopedia either.

We state this fact with regret. In many cases, the limiting factor is not excellence but simple visibility. Being part of the trans-Atlantic social science dialogue and engaging this dialog mainly in English translates into more visibility, as discussed earlier. This gets a scholar on the radar screen. Equally excellent work engaging other intellectual dialogues in languages other than English does not. A great many outstanding scholars have thus gone unrecognized in 2/e for precisely this reason. That being said, strenuous efforts were made to make the 2/e biographies more inclusive. Among those included are the Argentinean educationalist Sarmiento, the Brazilian sociologist Cardoso, and the Japanese political scientist Maruyama, to name just a few. This is, however, 'just a few' of the many dozens of prominent social and behavioral scientists 'out there' whom we would have included had we been given more time and more resources (to get non-English works translated, for example). We do feel that we have made some important inroads and beg the reader's understanding of the limits within which we worked. We can only hope that the next edition will strive for more inclusiveness and better representation than we were able to achieve.

Another entirely new feature in the 2/e biographies is the series of 'collective biographies.' In many instances, the intellectual lives of individuals who work in research groups intersect and form a network that makes the

entire group (or paradigm) successful. Examples include articles on the Durkheimians, the Annales School, the Frankfurt School, and several others.

As indicated earlier, instructions to authors were changed little from 1/e. All authors were asked (1) to include the most important biographical facts (country of origin, generation, education, influences, other formative experiences, networks, etc.); (2) to list the most important output (discoveries, publications, etc.) and to briefly discuss the subject matter and content of the most important publications or discoveries; (3) to look at the lasting impact of the person and his or her work (if possible, beyond just one discipline, language group, or culture); and (4) to provide a bibliography of primary and secondary sources related to the biographee and his or her work. Most authors stuck to these guidelines.

Finally, we state for the record that there are a number of important social and behavioral scientists that we would have liked to include but for whom we were unable to find a proper biographer. The search for biographers went on for nearly 4 years. In many cases, our first-choice author agreed at once, but in other cases, we approached four, five, or even more people before an agreeable author was found. And in about two dozen cases, no such author was ever found, with the result that a deserving person's biography had to be dropped. Forgoing a case-by-case discussion of these deletions, let it be simply noted that this is why we have not included biographies of people such as Amartya Sen, the economist and social philosopher; Raymond Boudon, the French sociologist; Ronald Dworkin, the legal theorist; Avishai Margalit, the philosopher; or a collective article for the British Marxist historians (Eric Hobsbawm, E.P. Thompson, Christopher Hill, and Perry Anderson). Perhaps our most regrettable omission is Neil Smelser himself, for whom no biographer could be found despite at least a dozen attempts. (Paul Baltes's biography is included.) Neil is one of the giants on whose shoulders we all stand.

Redundancy

I mentioned earlier that in the beginning of the project, there was no 'map' linking each of the 1/e articles to its respective 1/e Section. Our efforts to create such a map invariably bogged down every time we hit an article that could plausibly belong to any of several sections, which was often. Obviously, it would have been possible to force every article into a 2/e section, but at the time it seemed advisable to involve the editors themselves in these decisions. So on numerous occasions, I distributed lists of 'orphaned' articles (articles for which no home had yet been designated) to the area and section editors, asking for foster parents to volunteer. Eventually, of course, every article found a home, but at a relatively late date in the process, I became aware that a few dozen articles had found more than one home. That is, some of the editors adopted articles without filing the appropriate paperwork with the editor in chief! In such cases, the result was two articles on the 'same' topic. (The 2/e Table of Contents was scoured multiple times looking for precisely these kinds of duplications but in the end, several proved elusive.)

In the large majority of cases, the content of the 'duplicate' articles was sufficiently distinct that both articles were retained, often with some retitling to help readers differentiate between them. For example, readers will find two articles on 'social identity.' One was recruited for the section on social psychology; the other for the sociology section. With rare exception, the two articles discuss different aspects of social identity from entirely different disciplinary angles; indeed, the two articles share only a small handful of common references. So it was an easy decision to retain them both: one appears here as Social Identity in Social Psychology; the other as Social Identity in Sociology. Careful readers will find perhaps a score of similar cases in the encyclopedia.

Alas, in a few regrettable cases, the overlap between duplicate articles was so pronounced that one of the articles had to be deleted. Since by the time these problems surfaced the articles had (often) been written and rewritten several times and had been accepted by both the section and area editors, the last-minute decision to delete a redundant article was painful. My sincere apologies to the authors involved.

Some redundancy in a work of this scope and aspiration is not only inevitable, it is probably also desirable. A reader interested in, say, social inequality will (one hopes) want to know what the sociologists, anthropologists, economists, and geographers all have to say about that topic. And if a few of the many articles on the topic say more or less the same thing, then what harm is done? Editors at all levels were asked to be alert to redundancies across articles and the editorial record shows that many were. That being said, quite a bit of topical redundancy no doubt remains, and that is not (in general) a matter of concern. It is what Smelser and Baltes refer to as the "inevitable residue of overlapping."

The Review Process

Once the table of contents had stabilized, each of the editors was asked to review the 1/e articles assigned to their section or area and come to various decisions. In some cases, 1/e articles could be reprinted more or less 'as is,' with perhaps some updating of references for readers seeking entry points into the current literature. This was especially the case with what were eventually designated as 'legacy articles,' e.g., Gabriel Almond's article on Civic Culture, James Gregor's article on Dictatorship, &c. In other cases, the 1/e articles needed some updating to be suitable for 2/e, either by their original authors when available or by others recruited specifically for the purpose. The general rule was that all 1/e authors would be offered the opportunity to do the updates themselves, and that other authors would be sought in the event of the original authors' declinations. In still other cases, the 1/e article was so obsolete than an entirely new article would be required. And then finally, the review of 1/e articles often revealed areas of current research that were inadequately covered; in these cases too, completely new articles would be sought.

Where appropriate, the relationship between the 1/e and 2/e versions of an article is spelled out in the article tagline. In many cases, there were issues of authorship to resolve — a 1/e article written by *X* and completely revised by *Y* is *Y*'s article although *X* might be identified in the tagline; but what of an article written by *X*, now deceased, and only modestly revised and updated by *Y*? Every decision rule that I formulated to resolve such issues soon confronted an exceptional case where the rule did not seem to apply. So in the end, the only workable rule was that everyone should get proper credit for their intellectual property, whether prime author or reviser, whether living or dead. If exceptions to this rule have crept into the final product (as they almost certainly have), I offer my apologies to those whose work has been slighted or improperly recognized. Deciding on proper authorship for many of our articles was a far more involved and difficult task than expected.

The section editors formed the first line of editorial defense and were the ones to whom article drafts were originally submitted. The section editors read and commented upon the draft articles and returned them to authors for revision. It is a rare article that appears here in its original form: on average, articles were revised two or three times before being sent to the area editors and subsequently on to me; in many cases, it was more like five or six revisions, with subsequent revisions at the request of the area editors and the editor in chief. And in some cases, articles were submitted to outside readers for independent review. As I stated earlier, the reviewing process was not blind, but it was quite thorough, as is reflected in the exceptional quality of the final product.

Internationalism and Inclusivity

A truly *International* Encyclopedia of the Social and Behavioral Sciences would of course require a global network of editors and authors *and* a commitment to internationalize the content of the work wherever possible. With respect to the editorial team for 2/e, this was definitely realized. The section editors and editors in chief who produced the first edition were drawn from only nine countries: The United States, Germany, Italy, Canada, Sweden, Australia, France, Switzerland, and the UK. Two-thirds of those editors were from the USA and only 13% were women. Area and section editors for 2/e represent 21 countries, US scholars make up only 38% of the total, and women comprise 36%. Thus, the proportional representation of women among the editors was nearly tripled in 2/e over 1/e while the predominance of the USA was halved. Nations represented among the editors of 2/e that were not represented in 1/e include Luxembourg, Greece, Finland, Japan, China, Ireland, Singapore, Spain, Russia, Austria, Israel, and the Netherlands. The presence of several Asian nations on this list is particularly gratifying. To be sure, the North Americans and Western Europeans still predominate, but they no longer monopolize the field.

Adding the International Board of Consulting Editors (see the following statement of Acknowledgments) increases the internationalism of the editorial team even further. Of the 45 members of that Board, only 12 (27%) are US social and behavioral scientists. Countries represented on that Board that are not otherwise part of the editorial team include three Central and South American nations (Venezuela, Argentina, Costa Rica), several Asian nations (the Philippines, Malaysia, South Korea, India), a few Western European nations (Norway, Denmark), two representatives from Central and Eastern Europe (Hungary, Croatia), two from the Middle East (Lebanon, Qatar), and one from South Africa. These editions bring to 35 the total number of countries with representation on the IESBS editorial team.

Much the same can be said of the 2/e authors, who are also more international than the 1/e authors had been. Smelser and Baltes noted in their Introduction that while authors from 51 nations were represented in the work,

58% of the authors were from North America and another 35% were from (mainly Western) Europe. "As to gender composition, 21% of the [1/e] authors were women." In 2/e, the proportion of women among the authors has increased slightly to approximately 25% and the percentage of North American authors has declined to fewer than half. Again, North America and Western Europe still contribute the larger share of the 2/e authors but the growing representation of social and behavioral science authors outside the West is both noteworthy and encouraging.

Another important point is that the international scope of the project is much more pronounced than editors' and authors' current affiliations would lead one to conclude. (This would have been equally true in 1/e as well.) Consider, for example, Michiru Nagatsu, author of our article 03053 on the history of behavioral economics. Dr Nagatsu was born in Japan and retains Japanese citizenship but was educated at Exeter and the London School of Economics and Political Science and wrote his IESBS 2/e article while on a postdoctoral fellowship in Finland. Or Guillermina Jasso, area editor for Area Three. Jasso was born in the USA, received her PhD from Johns Hopkins, and is on the faculty at New York University. By any standard, she would count as a US sociologist in our compilations. Yet her parents were Mexican of Basque, Spanish, Portuguese, and Dutch origins; Spanish is her native language; over the course of her distinguished career, she has published with coauthors from Germany, India, Israel, Mexico, the Netherlands, and Sweden; and she holds a permanent research fellowship at IZA, the Institute for the Study of Labor, in Bonn, Germany. Scoring her as 'USA' scarcely does justice to her biography or to the international perspective she brought to the editorial task.

What is true of author Nagatsu and editor Jasso is true in degrees of virtually the entire roster of IESBS participants. If one includes place of birth, citizenship, where educated, sites of research, visiting appointments, sites of fellowships, honorary professorships, invited lectures, and on through the list of highlights in a modern academic career, it is safe to say that every nook and cranny of the globe (save, possibly, Antarctica) is represented somewhere in the biographies of IESBS authors and editors. The true measure of internationalism, in short, is not so much where people come from or where they currently are, but rather the extent to which they bring a sensitivity and commitment to cultural and national differences into their work. Whether this was or was not realized in 2/e is for readers to decide.

Concluding Observations

Smelser and Baltes aspired in the first edition of this work to "assemble the whole range of knowledge – vast and complex as it is – of the social and behavioral sciences in one place." Since what does and does not qualify as 'social and behavioral science' is itself contested, it is not surprising that nearly every one of the market reviews commissioned by Elsevier to guide the development of the current edition noted content omissions in 1/e that reduced its usefulness and that needed to be addressed in a second edition. Critics can and no doubt will say the same about 2/e. I have already mentioned the nearly 800 articles that appeared on the 2/e Table of Contents at one time or another but that will not be found in the final product, either because agreeable authors could not be located or (less often) because agreeable authors never produced an acceptable article. And it is pretty easy to identify whole chunks of present-day social and behavioral science that are given short shrift, or no shrift at all, in this work – not because these chunks were judged to be unimportant but because limits of time, space, resources, and networks meant that some elements of the contemporary social science enterprise never came to our attention.

The social and behavioral sciences begin with what artificial intelligence guru Marvin Minsky once described as a "three pound computer made out of meat" – the human brain, which for all we know is the most complicated three-pound hunk of matter in the universe – and end with a thoroughly globalized culture and social structure that encompasses all aspects of our species' physical, biological, psychological, social, emotional, cultural, and spiritual lives. We are the most successful species ever to have inhabited the planet; we have colonized every inhabitable piece of dirt; our range extends everywhere; all the earth's resources lay at our command. To record all that has come to be known about human origins, evolution, language, culture, and social structure – everything we know about human emotions, identity, love, religion, family, economics, politics, domination, exploitation, and on through a very long list – would require orders of magnitude more volumes than the mere 26 volumes that comprise the present work.

We have come increasingly to the realization that what is social and human about our species is very intimately connected to our biological, genetic, and evolutionary inheritance. At the same time, the brain specifically and biological evolution more generally "cannot be viewed separately from the material, historical and

social circumstances that produce it" (Berntsen and Baker, 2015). As these authors put it, biology and culture are 'mutually constitutive.' Fifteen years ago, the editors of the first edition remarked on "ferment at the boundaries between the biological and the behavioral and social sciences." And while there are still important controversies, much of the ferment has yielded to cooperation as we are just now beginning to explore this endlessly complex web of interconnectedness between our biological and social selves. It is an easy and nearly inevitable conclusion, thus, that the third edition of the IESBS will contain a great deal more of the work being done at this intersection than 2/e was able to accommodate.

To conclude on a purely personal note, the 5 years I have spent working on this project produced many professional and personal gratifications, none quite so delicious as the certain knowledge that I would learn something new every single day. My work on 2/e exposed me to literature I never knew existed and to aspects of the social and behavioral sciences of which I was at best dimly aware. I can only hope that readers who come to these pages will find them as enriching as I have.

ACKNOWLEDGMENTS

A work of this scale is inevitably a communal enterprise involving many hundreds of editors, authors, reviewers, technical support people, colleagues, professional acquaintances, and friends who have provided input, advice, encouragement, and assistance over the past five years. Any listing is bound to be incomplete, so my apologies in advance to those who expected to be mentioned here but are not. Be assured that the slight is not intentional.

My negotiations with Elsevier about this project began early in 2010. By May of that year, I had committed to the project and have been working on it at varying levels of intensity ever since — often on weekends, during holidays, and whenever else I could snatch a useable chunk of time. So my first acknowledgment must be to my wife Chris for suffering through my five year obsession, always with understanding and affection, usually with good cheer. Chris is probably the only person in the world who is happier than I am that the project is now completed.

I must also acknowledge an enormous intellectual debt to the editors in chief of the first edition of the *International Encyclopedia of the Social and Behavioral Sciences*, Drs Neil Smelser and Paul Baltes (the latter now deceased). Dr Smelser was gracious enough to serve as Chair Emeritus of the project's International Board of Consulting Editors and to put himself at my disposal as, in his words, "a battle-scarred veteran." The basic intellectual structure of this work is adopted more or less wholesale from the Smelser—Baltes edition, with a few exceptions noted earlier in the *Introduction*. Without the original to serve as the starting point and blueprint, it is hard to imagine even embarking on such a task, much less bringing it to completion. Their edition was hailed as "the largest corpus of knowledge about the social and behavioral sciences in existence," which is to say that it formed an *extremely* solid foundation from which to build the work you now hold in your hands.

The first edition was organized into 39 sections overseen by a team of 53 section editors. The structure of the second edition is slightly different. It is divided up into 10 broad 'Areas,' each with an Area Editor overseeing the work of between four and eight Section Editors. In all, the second edition is thus comprised of the 10 Areas subdivided into 53 Sections; the 53 Sections were developed by a team of 76 Section Editors. So whereas Smelser and Baltes had 53 colleagues to help complete the work, I had 84 (two of the Area Editors also edited their own sections). On pages i-v in the front matter to this work one finds an Editorial Board list showing the Area Editors, Section Editors, Sections, names, and affiliations of the entire editorial team — a team whose dedication and effort in behalf of the project has vastly exceeded the rate of pay. A more helpful, productive, or delightful group of scholarly collaborators is difficult to imagine.

What readers see in the listed Editorial Structure of the work is the *final* editorial team as it existed when the work went into production. As would be expected in a project of this duration, there was considerable turnover within the team as the project developed and as death, competing demands, and general indifference all took their toll. I am grateful, nonetheless, to everyone who agreed, at least initially, to participate in the project, whether or not they were able to stay involved to the very end.

Susan Hanson (Geography) and Ulf Hannerz (Anthropology) are owed a special note of thanks because, of the 53 Section Editors involved in the first edition, these are the only two who agreed to reprise their roles in the second. (Both also wisely requested and received coeditors to carry part of the load.) Persuading people to serve who had no real idea what they were getting into was challenge enough, but these two suffered through 1/e and were willing to do it all over again for 2/e. And for that, I am especially grateful.

Many of the editors benefitted from the assistance of colleagues and graduate students at their various institutions. There was no mechanism built into the editorial process to keep systematic track of this

assistance and so the listing below is certain to be incomplete. But I can at least acknowledge those of whom I am aware who contributed time and intellectual energy to the effort: Liam Morton and Andrea Livingstone (Psychiatry); Jennifer O'Connor and Alana Dorris (Applied, Industrial and Organizational Psychology); Jen Hanis-Martin (Sexuality); David Budde, Annette Stimmer, Nikolas Ott, and Franziska Pfeifer (Institutions and Infrastructure of Social and Behavioral Sciences); Matthew LeDuc and Scott Freeman (Contemporary Cultural Concerns); and Simone Dudziak (Public Policy). To those named, my thanks. To those omitted, my apologies.

A special note of thanks to Dr Donald J. Barrett. Don was originally recruited to develop an entirely new section of the second edition on Gay, Lesbian, Bisexual, and Transsexual Studies, completed the section in short order, then e-mailed me to ask if there was anything further he could do to be helpful. Consequently, he took a major hand in developing the section on Biographies and was quite helpful with many other sections too. He appears in the Editorial Structure both as a Section Editor and as a Senior Editorial Associate to acknowledge his yeoman service to the entire enterprise. Also listed as a Senior Editorial Associate is my colleague Dr Amy M. Donley, who has been with the project since the very beginning and who, more than once, was all that stood between me and madness. I am proud to count them both as colleagues, collaborators, and friends.

I am also pleased to acknowledge Don Barrett, Andreas Hess, Harry Whitaker, John Berry, Barbara Miller, Scott Bentley, and Claire Byrne for their incisive and helpful commentary on previous drafts of the Acknowledgments and Editor's Introduction.

The project's International Board of Consulting Editors, chaired by Smelser and Dr Peter Marsden of Harvard University, was formed late in 2011 as a 'sounding board' to be used by the Area and Section Editors in searching for topics and authors and to help push for greater internationalism in our coverage. As it turned out, several members of this Board also stepped up to write entries in their areas of expertise. The composition of this Board and the affiliations of the consulting editors (as they were when the Board was first formed, not necessarily as they are today) are as follows: Neil J. Smelser, *University of California, USA*; Peter V. Marsden, *Harvard University, USA*; Ronald F. Abler, *International Geographical Union, USA*; John Bacon-Shone, *University of Hong Kong, China*; Roberto Briceño-León, *Universidad Central de Venezuela, Venezuela*; Roel Bosker, *Rijksuniversiteit Groningen, The Netherlands*; Michael Burawoy, *University of California, Berkeley, USA*; Nestor T. Castro, *University of the Philippines, Philippines*; Dalton Conley, *New York University, USA*; Freek Cronjé, *North West University, South Africa*; Scott Davies, *McMaster University, Canada*; Abdul Rahman Haji Embong, *Malaysian Social Science Association, Malaysia*; Joan-Maria Esteban, *Barcelona Graduate School of Economics, Spain*; Robert S. Feldman, *University of Massachusetts, USA*; Sari Hanafi, *American University of Beirut, Lebanon*; Gudmund Hernes, *Norwegian Business School, Norway*; Sheila Jasanoff, *Harvard University, USA*; Tim Jensen, *University of Southern Denmark, Denmark*; Colin Jones, *University of London, UK*; Nadezhda Lebedeva, *Higher School of Economics; and National Research University, Russia*; Miklós Lévay, *Eötvös Lorand University, Hungary*; Dinka Marinovic Jerolimov, *Institute for Social Research, Croatia*; Laurie M. Joyner, *Rollins College, USA*; Ferenc Kiefer, *Hungarian Academy of Sciences, Hungary*; Pan Suk Kim, *Yonsei University, South Korea*; Katsuya Kodama, *International Peace Research Association; and Mie University, Japan*; Allan Lavell, *Facultad Latinoamericana de Ciencias Sociales (FLACSO), Costa Rica*; Jake Lynch, *University of Sydney, Australia*; Cecilia Mabragana, *Consejo Nacional de Investigaciones Cientificas y Tecnicas (CONICET), Argentina*; William McBride, *Purdue University, USA*; Ishwar Modi, *University of Rajasthan, India*; Leonardo Morlino, *School of Government, Italy*; Melvin L. Oliver, *University of California, USA*; Angela M. O'Rand, *Duke University, USA*; Kenneth Prewitt, *Columbia University, USA*; Thilo Rehren, *University College London Qatar, Qatar*; Colette Sabatier, *Université Victor Segalen, France*; Philip Schofield, *University College, UK*; Rainer K. Silbereisen, *University of Jena, Germany*; Chamhuri bin Siwar, *National University of Malaysia, Malaysia*; Tom W. Smith, *World Association for Public Opinion Research, USA*; Catalina Smulovitz, *Universidad Torcuato Di Tella Miñones, Argentina*; Philip Spinhoven, *Leiden University, The Netherlands*; Sukhadeo Thorat, *Indian Council of Social Science Research, India*; Nigel Thrift, *University of Warwick, UK*; John R. Townshend, *University of Maryland, USA*; Gisèle Yasmeen, *Social Sciences and Humanities Research Council of Canada, Canada*.

Searching for an editorial team to represent every social science discipline and every region of the globe quickly exposed the deficiencies in my personal network, so I am indebted to a very large number of scholars around the world for calling names of prospects to my attention, allowing me to drop their names in the recruitment effort, or otherwise helping me find people with the expertise and commitment required for the job. In most cases, this is a list of people who were invited onto the editorial team in some capacity,

demurred, but made valuable suggestions about others to contact. In several cases, people are listed because they engaged me in intellectual discussions about the structure, format, and even advisability of this work, or simply replied to a cold-call e-mail in pleasant, kind, helpful, or informative ways. Again ignoring the risk of omission, my sincere personal thanks to those named below for their contributions large and small to the final product:

Doug Anderton, Juri Allik, George Armelagos, Susan Ayers, Amanda Baumle, Janeen Baxter, Jess ben-Habib, Joao Biehl, David Blanchflower, Hans-Peter Blossfeld, Jason Boardman, Dorret Boomsma, Roel Bosker, Henry Brady, Martin Bulmer, Craig Calhoun, Miguel Centeno, William Cockerham, Mark Nathan Cohen, Amelie Constant, Simon Cottle, Connie Citro, Eileen Crimmons, James Curran, Scott Davies, Donatella Della Porta, George Downs, Francis Dodoo, David Dozois, Sonja Drobnick, Jaap Dronkers, John Dryzek, Riley Dunlap, Lauren Edelman, David Elesh, Paula England, Nancy Eisenberg, Geoffrey Evans, Miriam Faust, Robert Feenstra, Marcus Feldman, Stanley Feldman, Ronald Fischer, James Fowler, Jeremy Freese, Angela D. Friederici, Michael Frumpkin, Masahisa Fujita, Nicole M. Gage, Nancy Gallini, Rosemary Gartner, Morton Ann Gernsbacher, Robert Goodin, John Grattan, Lance Gravlee, David Greenberg, Wendy Griswold, Melanie Guldi, Monica Das Gupta, Peter Hatemi, Robert Haveman, Karen Heimer, John Hibbing, Sarah Blaffer Hrdy, Sheila Jasanoff, Kelly Kadera, Cigdem Kagitcibasi, David Kavanaugh, Roger Keil, Byungkook Kim, Rob Kitchin, Jack Knight, Lyle Konigsberg, Candace Kruttschnitt, Helen Ladd, Phillip Lane, Graeme Lang, Janet Lauritsen, Ashley Leeds, Evelyn Lehrer, Richard Lerner, David Lewis, Tim Liao, Tom Linneman, Norman Long, Karen Lyons, Ruth Mace, Gary Marks, Herbert Marsh, Karl-Ulrich Mayer, Lorraine Mazerolle, Rose McDermott, Susan Michie, Harry Minas, Peter Miller, S. Phillip Morgan, Victor Nee, Vin-Kim Nguyen, Paul Nieuwbeerta, Helga Nowotny, Howard Nusbaum, Claus Offe, Thomas Ollendick, Joan Orme, Dennis O'Rourke, Michael Overington, Catherine Panter-Brick, Susan Parnell, Deborah M. Pearsall, Gerard Pfann, Jon Pierre, Mike Ping, Jennifer Platt, Ken Prewitt, Cathy Price, Jill Quadnagno, Charles Ragin, Thilo Rehren, Ben Rosamond, Bo Rothstein, Beth Rubin, Heinrich Sauer, Peer Scheepers, Ralf Schwarzer, Moshe Semyonov, Michael Shanahan, Sara Shostak, Alan Sica, Rainer K. Silbereisen, Beth Simmons, Catalina Smulovitz, Michael Sobel, Diane Stone, Jill Stephenson, Rafe Stolzenberg, Miron Straf, Richard Swedberg, Alan C. Swedlund, Sidney Tarrow, Jacques-Francoise Thisse, Stefan Timmermans, Florencia Torche, Erik Tsang, Judy Treas, Billie Turner, Cees van der Eijk, Paul van Lange, James Vaupel, Karin Wahl-Jorgensen, Mitchell G. Weiss, Neil Whitehead, Pamela Wilcox, Bjorn Wittrock, Cornelia Woll, Gisele Yasmeen, and Barbie Zelizer.

Gratitude is owed as well to the many colleagues at Elsevier who contributed to the production of this volume. My first debt is to Claire Byrne, the project's Content Project Manager and the head of the Major Reference Works (MRW) team that managed the day-to-day *Sturm und Drang* of the project: aggrieved, confused, or delinquent authors, missed deadlines, testy and intransigent editors, and the often-maddening work style of the Editor in Chief. I am sure there were days when Claire wanted to tear her hair out, but to external appearances, she was an island of calm in a sea of turmoil. She was also exceptionally good at her job.

Claire's MRW team comprised Richard Berryman, Will Bowden-Green, Esmond Collins, Mark Harper, Sam Mahfoudh, Mike Nicholls, Gemma Tomalin, Joanne Williams, and Marise Willis. No matter what issue or problem I faced, one of these fine, capable people was always available to step up with a solution, invariably offered in a spirit of cooperation and good cheer. They have been to IESBS 2/e what tech support is to the modern computerized office. Getting this work completed without their help is inconceivable.

Thanks also to the succession of Elsevier's Acquisitions Editors who managed the finances and internal politics of the project: to Scott Bentley, whose gentle suasions pulled me into the project in the beginning; to Karen Maloney and Peter Labella who ran the show in the middle period; and to Lisa Tickner who was in charge at the very end. These are the people on the front line in the endless war between the publisher, who wants things done now and at minimal expense, and the Editor in Chief, who was always asking for more time and more money. The many dozens of amicable compromises necessary to bring the project to completion were all ably negotiated by Scott, Karen, Peter, and Lisa, and for that, I am grateful indeed.

The University of Central Florida and its Department of Sociology have provided a congenial home for the project. My thanks in particular to Dean Michael Johnson; to the current and former chairs of my department, Jana L. Jasinski and Libby Mustaine; to my faculty colleagues Liz Grauerholz, Phillip 'Hutch' Pollock, Bruce Wilson, Melanie Guldi, Stacy Barber, Tosha Dupras, and John Schultz; and to current and former graduate students Thomas Hall, Sara Strickhouser, Betsy Swart, Jordana Navarro, Marie Gualtieri, Shannon Simone, and Shannon Frey.

And most of all, my sincere thanks to the many thousands of authors whose work this is. When comparing the quality of the work contained within these pages to the authors' honoraria, it is obvious that IESBS 2/e is an act of collective charity by our authors to the disciplines they represent. It is my pleasure to thank our authors on behalf of the global social science community.

James D. Wright
Orlando, Florida
January 2015

GUIDE TO USING THE ENCYCLOPEDIA

Structure of the Encyclopedia

The material in the Encyclopedia is arranged as a series of articles in alphabetical order.

There are four features to help you easily find the topic you are interested in an alphabetical contents list, cross-references to other relevant articles within each article, subject classification index, and a full subject index.

1. Alphabetical Contents List

The alphabetical contents list, which appears at the front of each volume, lists the articles in the order that they appear in that volume of the Encyclopedia. It includes both the volume number and the page number of each article.

2. Cross-references

All of the articles in the Encyclopedia have been cross-referenced. The cross-references, which appear at the end of an article as a See also list, serve three different functions:

a. To draw the reader's attention to related materials in other articles.
b. To indicate material that broadens and extends the scope of the article.
c. To indicate material that covers a topic in more depth.

3. Subject Classification Index

This index appears in Volume 26 and groups articles under subject headings that reflect the broad themes of Social and Behavioral Sciences. This index is useful for making quick connections between articles and locating the relevant article for a topic that is covered in more than one article. Under some section headings, you will find subheadings, if it is appropriate for the articles in a subject area to be grouped into more specific subareas.

4. Contributors

At the start of each volume, there is list of the authors who contributed to that volume.

5. Index

The index appears in Volume 26. The index includes page numbers for quick reference to the information you are looking for. The index articles differentiate between references to whole article, a part of an article, and a table or figure.

Abstract

The article provides an overview since the starting point of the field in the mid-1960s, its main developments, strengths, and weaknesses and suggests new research avenues.

Introduction

The two landmarks of art history and economics, Johann Winckelman's *Geschichte der Kunst des Altertums* and Adam Smith's *An Inquiry into the Nature and Causes of the Wealth of Nations*, are almost contemporaneous. This should have paved the way to a good understanding between the two emerging disciplines. Unfortunately, they did not, though most forefathers of the science that came to be called 'economics' made forays into 'art.' Most of them were concerned with art as a 'luxury' or as the object of 'conspicuous consumption'; prices; talent needed to create; 'progress' in the arts; why people buy art; why competition is needed; exorbitant rewards; copyright; public support of the arts (or its regressive nature, since anyway, art is for the riches); moral utility of the arts, and so on, but aesthetics and art history were far from being important in the discussion (Goodwin, 2006).

Research on the economics of art really started with the essay by Baumol and Bowen (1966) on why, unless they receive financial support, the performing arts may disappear. In a nutshell, today as in 1750, a quartet needs four musicians, and while there may be productivity gains in the rest of the economy, and therefore, wage increases, they will also have to be passed through to musicians. Otherwise, nobody will be attracted to become a professional musician, and quartets will disappear. If, on the other hand, these wage increases are passed through to musicians, and since no productivity gains can be made, quartets will become too expensive to run and will also disappear. Therefore, intervention (public or other) is needed. Many arguments have been suggested to counter this theory that came to be called 'the cost disease, but it still has a lot of appeal and generated a large literature.

The field is now reasonably well established, has an association, the Association of Cultural Economics International, publishes a quarterly journal, the *Journal of Cultural Economics*, organizes, every other year, a conference that is attended by 200–300 scholars, and has been able to generate teaching positions in a few economics departments in Europe and in the United States. Though the discipline is now the subject of several handbooks and collections of articles (Ginsburgh and Throsby (2006, 2013), Towse (2003, 2008a). See also Frey and Pommerehne (1989), which contains a very complete and useful list of references written before 1989.), it is still in its infancy and, as will be discussed, is looking for some firm ground.

Indeed, the subject is hard to define, since it is located at the crossroads of several disciplines: art history, art philosophy, sociology, law, management, and economics. It also started to make forays into topics that used to be discussed in other fields, such as anthropology, development economics, cultural conflicts, psychology, religion and customs, and languages. These extensions will not be discussed here. (The interested reader is encouraged to visit Hutter and Throsby (2008) and Ginsburgh and Throsby (2013).)

The issue of whether economists interested in cultural economics should simply apply their usual tools to questions related to and data coming from the arts, or whether they should take culture as an opportunity to add new issues to the existing economic literature is still open. Should economists take as granted that prices and income are the main determinants of the demand for theater plays or should they also understand what quality means in such heterogeneous markets, define it, measure, and enter it as a variable in their empirical models? Blaug (2001) concludes in a pessimistic way: "We have all been hoping that the field might actually suggest and promote developments that would spill over with benefit to economics outside its own domain. Has this happened? Not really." Not only did nothing spill over from art or cultural economics to economics in general. But there is worse, since many tools are or have been 'invented' and imported from economists who certainly have some feeling for art and culture, but whose main field of research was or is different. We shall give some examples later, but here are some articles that are worth singling out: Stigler and Becker (1977) who emphasized rationality in cultural consumption; Montias (1982, 1996, 2004) and his choice of looking at inventories and other microdata to analyze painters and collectors in the Dutch seventeenth-century Golden Age; Rosen's (1981) superstar model showing that small differences in talent make for large differences in income; Baumol (1986) who suggested that the difference between the returns on art and financial markets could be interpreted as accounting for the aesthetic pleasure provided by looking at artworks; Ashenfelter (1989) who made auctions known outside of the difficult theoretical field in which they were entrenched and made economists who were interested in the arts aware that hammer prices could be used to estimate price indices; and Peacock for his many contributions, but especially for his *Paying the Piper* (1993).

We start our discussions with two topics that are of concern to all types of art: Should the arts benefit from public or private support and from regulation (Section Public Support of the

Arts) and How well labor markets for artists work (Section Labor Markets and Artists' Careers). Next we go to specific problems, distinguishing the visual arts (paintings, sculpture, art objects) in Section The Visual Arts, the performing arts (music, theater, opera, dance) in Section The Performing Arts, and cultural heritage (museums, historical buildings, monuments, and sites) in Section Cultural Heritage, Where Do We Go, though there are some unavoidable intersections (museums accumulate paintings, some artists in the visual arts produce unique performances in galleries). There is a tendency, nowadays, to add what came to be called the cultural (or creative) industries, which are interested in books, movies, popular music, records, the media, the internet, and copyright, and are very briefly discussed in Section The Cultural and Creative Industries. In each case, we try to point out what cultural economists have found interesting, discuss the tools that they have imported from economics to analyze art and culture, and some issues that are still open. Section Concluding Remarks concludes.

Public Support of the Arts

Many arguments have been invoked to justify public support and correct for assumed market failures. Some arguments hold for all forms of artistic activity (including the cultural industries), some are more specific. Here is a nonexhaustive list of the most important economic rationalizations for such support.

1. The oldest and most often invoked argument is that art, whatever its form, is a public good. It benefits not only those who see it and who pay for it but also all other consumers, who do not necessarily wish to contribute voluntarily to its production (performing or visual arts) or to its preservation (museums) and free ride or who cannot contribute, since they are not yet born (heritage). If the arts are left to the market, they will not be priced correctly and will thus be underproduced or not saved for future generations. Artistic activities are also said to produce externalities that cannot be sold on the marketplace, such as civilizing effects, national pride, prestige, and identity (justifying, for example, the French position in its fight against free trade of movies and TV programs), social cohesion, and so on, which benefit all consumers. Similar arguments had already been suggested by Stanley Jevons, Adam Smith, and Arthur Pigou.
2. But the arts are also said to yield economic externalities. Old castles, well-known opera houses or orchestras, and art festivals attract visitors and tourists. So do museums with good collections, while newly constructed museums are claimed to contribute to city renewal (an argument used, for instance, to attract public support for the Guggenheim museum in Bilbao). This is supposed to have spillover effects on hotels, nearby restaurants, and shops, generate new activities and came to be called the 'arts multiplier' (see Grampp, 1989: p. 247).
3. Art is a 'merit' good. It "is a means of educating the public's taste and the public would benefit from a more educated taste" (Scitovsky's, 1972). Since consumers are not fully informed, they are unable to evaluate all its benefits without public intervention. Moreover, even if there is addiction to the arts, it develops only slowly, and consumers have to be exposed as much as possible.
4. For equity reasons, art should be made available also to low-income consumers who cannot afford to pay. Poor artists should be supported alike. Schemes for doing this will be discussed below.
5. Culture is transmitted by education but also from parents to children. Since parents can hardly be considered as purely altruistic, an additional externality is generated, which needs support for efficiency (and equity) reasons.
6. The last argument on the difficulty or impossibility to achieve productivity gains is more specific to the performing arts: the Baumol cost disease, which we discussed earlier as being the starting point of cultural economics.

These issues have of course their supporters and their detractors, the most enjoyable to read being Grampp (1989). Detractors base their case on the public choice theoretic claim that some people wish to use the state's resources for their own benefit and on the regressive nature of supporting high-income groups who are more likely than others to attend and who can afford to do so. In 1997, in the United States, for example, 35% of the high-income population (more than $75 000 per year) attend classical music live performances, while this percentage drops to 6.8% for the lowest income group. See Heilbrun and Gray (2001: p. 47). See also Benhamou (2000) for Europe.

The cost disease has led to a host of quantitative studies, which show that the curse is not as severe as what Baumol and Bowen had originally suggested. Empirical studies on the performing arts point to price elasticities which are smaller than one so that there is still some room for price increases; bundling – bookstores at opera houses, museums, drinks during intermissions – can also be used more systematically; technical progress (sound and lighting, for instance) can make for larger audiences; broadcasts and records could be used to cross-subsidize live performances, and make these less expensive; opera music is performed under the form of concerts, and both are broadcasted in real time; contemporary theater plays save on the number of characters, and so on. See Towse (1997b) for a collection of papers on the disease.

In most developed countries, the arts are supported, though the volume of public intervention can vary substantially. It is very low in the United States ($3–4 per head), reaches $16 in the United Kingdom, $19 in Australia, and $30–40 in Continental Europe where private support is negligible. (See Throsby, 1994: p. 21 as well as Netzer, 1978 for more detailed data.) No convincing argument has yet been put forward to explain these large differences in behavior between the Anglo-Saxon and other cultures.

Government intervention takes several forms. It can be direct: Some art institutions or companies are state-owned (museums in most European countries, but also opera companies, theaters, symphony orchestras) and are, therefore, supported, at least in part, by public funds. Their efficiency has been questioned on many occasions. Arts education programs are also often supported by the state. In the 1960s, Peacock (1993: p. 122) suggested to distribute to poor consumers art vouchers exchangeable for seats or visits to museums.

In most cases, public funds, including lottery funds, are channeled to companies, or directly to artists, through subsidies or tax relief (reduced VAT rates, no or lower rates of taxation on profits or on income). In the United States, most of the effort is concentrated on tax deductions or exemptions to donors (individuals or corporations) for charitable contributions; gifts or bequests of artworks are also encouraged by tax concessions, and more and more often, inheritance taxes can be paid for by artworks. This indirect subsidization system is much less used in European countries, though similar incentive schemes are present. See also O'Hagan (1998) for more information.

The less direct (and, sometimes, most insidious) form of intervention is regulation, which is mainly concerned with (1) ensuring moral rights, that is, protecting artists against being plagiarized, or against alterations or destruction of their works; (2) ensuring financial rewards to living artists and to their heirs during as much as 70 years after their death under the form of copyright. Copyright has led to a very large literature, at the confines of law and economics. See Landes and Posner (2003) and Towse (2008b) for a collection of recent articles. Its economic justification is based on the idea that it provides incentives to create and that the absence of protection would lead to underproduction. (Waldfogel (2011a,b) shows that this is wrong in the music industry.) The same idea is used to justify protection of industrial patents.

Copyright applies mainly to plays, literary, and musical works. Authors usually do not 'sell' their creation, but get compensated through authors' rights for each copy (book or record) sold or for each performance of a play or of a score. However, the idea has been extended to all other forms of art, including the performance itself (the staging of a play can be copyrighted and so do live performances by visual artists), and the visual arts. Reproduction of a work pays rights to the artist even after he sold it. One can wonder whether copyright laws still provide incentives for art creation, or whether they generate incentives to use Mozart's music in movies and Schiele or Klimt paintings (no longer covered by copyright) to illustrate book covers. Obviously, regulation has led to overregulation, much more driven by the rent-seeking behavior of the music industry and author societies than by artists.

The international trade of cultural goods has also attracted the attention of regulators. Some countries fully prohibit the export of artifacts of some age – although illegal exports from Africa, Mexico, Italy, or Greece keep going. Some countries (France and the United Kingdom) are more lenient and require export licenses for 'national treasures'; this procedure is often used to delay the export and give time to the potential exporting country to raise funds and buy the object at the price at which it could be sold abroad. France insists on maintaining import quotas on American TV programs to 'protect' local culture and national identity. This is the so-called cultural exception argument, which is very reminiscent of its forefather, the infant industry argument.

Labor Markets and Artists' Careers

A folk theorem states that most artists are poor – or have lower income than the average consumer, die poor, while salerooms, their dealers, and editors become rich.

Using the 1980 US Census data, Filer (1986) concludes that, on average, artists do not earn any less than they would in a nonartistic employment. It has later been shown, however, that this is due to multiple job holdings, including in nonartistic activities (Wassal and Alper, 1992). If these extra jobs are not accounted for, artists' average incomes are smaller than those of workers with comparable education. It is also said that artists devote less time to their work on art than do others to their main occupation, that they may have to go to lower paid jobs to supplement their income, and that their earnings are more variable and less directly influenced by education than those of other workers. To explain why artists accept this income differential, one has to appeal to differences in motivation; this is summarized by Throsby (1994: p. 17) for whom "the primary desire to create art as a principal occupation must be recognized as the essential driving force behind an artist's labor supply decisions."

But the income distribution of artists is also markedly skewed and there exist superstars, whose earnings are impressive. Rosen (1981) shows that talent only does not explain these differences. He models income as a convex function of talent so that small differences in this endowment may result in large differences in income. This is compounded by the fact that there is little if any substitution between various degrees of talent or between quality and quantity. As Rosen points out, "hearing a succession of mediocre singers does not add up to a single outstanding performance."

In a series of articles and a book, Galenson (2001) studies the careers and life cycles of impressionist and modern French and American painters (as well as writers) and consistently finds that some artists bloom early, while others produce their best works later during their life cycle. The two types of careers are related to innovative behavior. *Conceptual* artists, who bloom early "think of [their work] as primarily making a preconceived image, and [the execution is] often simply a process of transferring an image they have already created from one surface to another." *Experimental* artists, on the other hand, bloom late: "Their goals are imprecise, so their procedure is tentative and incremental" (Galenson, 2003). The idea that some artists bloom early, while others are late, and that artists may follow two paths in their creative work seems very reasonable. What is less so is the association between age and type of creativity and the dichotomous behavior of being either conceptual or experimental; most artists are both at different times in their careers and even at the same moment in different works. See Ginsburgh and Weyers (2006) and Simonton (1997).

The Visual Arts

Art works are, with some exceptions, heterogeneous. Each creation is unique and markets can hardly be analyzed by the usual supply–demand mechanism. The very high prices reached by some works has led economists to study (1) what can be said about the characteristics that determine values, (2) whether the returns obtained on artworks outperform those of financial markets, and (3) why tastes change. None of these issues has been given a definitive answer.

Values are obviously mainly determined by the name (or the reputation) of the artist, but this explains little, and one should understand why reputations differ. Decomposing 'quality' in terms of (hopefully) objective characteristics or properties should be possible. After all, this is what the French art historian de Piles (1708) had in mind and led him to grade on a scale between 0 and 20, characteristics such as composition, drawing, color, and expression, for a group of painters, and rank them accordingly. Analytic art philosophers have developed the idea of properties, which is quite close to economists who work on horizontal and vertical differentiation, so that there is some common ground.

Financial returns on works of art have been analyzed very often (see Frey and Eichenberger, 1995 and Ashenfelter and Graddy, 2006 for surveys), but Baumol's (1986) article was probably the most influential one. Baumol finds that between 1650 and 1960, the average real return rate is equal to 0.55% per year, some 2% lower than the return on bonds. He suggests that the difference is attributable to the return provided by aesthetic pleasure.

Tastes change, and prices commanded by works of art often follow these movements. There are many examples of painters who have been 'rediscovered,' including Botticelli, Vermeer, Goya, or the Pre-Raphaelites. See Haskell (1980) for an account of these changes in France and in the United Kingdom between the late eighteenth century and the early 1920s. It is unclear whether such changes are due to fads or fashion or to more fundamental reasons. Grampp (1989: pp. 66–68) suggests that the rapid succession of styles in contemporary art is due to the rapid increase in consumers' income, "who seek novelty more often than they would if their income was lower." Montias, an economist turned to famous art historian, respected for his work on Vermeer and on Dutch Golden Age painting. See among others Montias (1982). Instead of analyzing leading figures and facts, his work centers on ordinary people. In his 1996 analysis on seventeenth-century Dutch art collectors in Amsterdam, he illustrates how quantitative methods can be used in art history. He also uses archives to examine the intricate relations between artists, art dealers, and their patrons and shows that dealers were only modestly successful. They relied on friends, business as well as religious acquaintances, and their family for their working capital, of which they seemed to be in constant need. Their role in dealing works by the major artists of their time seems also to be quite limited (Montias, 2004). Much work in similar directions is described in the articles jointly written by economist de Marchi and art historian Van Miegroet. Their articles on copies (1996), on early auction markets (2004), and more generally on economic art history (2006) should be singled out. So should the book by Nelson and Zeckhauser (2008), who use information economics to understand art markets from the Italian Renaissance.

The status and the prices of copies (to be distinguished from fakes) have also varied over time. While copies were close substitutes for originals during the seventeenth century, and priced at about half the price of originals (De Marchi and Van Miegroet, 1996), they are hardly considered to have any value nowadays. Again, little is known about the reasons and the period at which the break occurred. (See Benhamou and Ginsburgh, 2006.)

Many issues discussed above have often been analyzed on the basis of works sold and prices obtained at auctions. This has led to several observations on the possible inefficiency of auction mechanisms, which theory considers to be efficient. Among these observations, let us single out the declining price anomaly (prices of homogeneous lots sold in sequence decrease over time), but this is also the case for the ratio between hammer prices and presale estimates for heterogeneous works of art (Ashenfelter, 1989; Beggs and Graddy, 1997), the existence of systematic price differences across salerooms and/or countries (Pesando and Shum, 1996), the biasedness of presale estimates by salerooms and the fact that presale estimates do not reflect all the information that is available to them, though theory shows that it is efficient for the auctioneer to reveal the truth (Bauwens and Ginsburgh, 2000).

The Performing Arts

The performing arts were the first to be studied after Baumol and Bowen (1966) introduced their cost disease alluded to earlier. Blaug (1976) contains a collection of papers written in the late 1960s and early 1970s that are mainly devoted to the performing arts. See also Throsby and Withers (1979). It is also the sector that can be thought to conform best to the classic supply–demand framework. Demand is modeled as depending on own price, prices of substitutes, income, quality, and the 'price of leisure,' since the performing arts are time consuming.

However, both quality and the price of leisure are usually difficult to assess (Throsby, 1983). Supply is multidimensional and can hardly be represented by the number of seats or the number of performances offered. Indeed, what is offered is also variety and width of repertoire, categories of seats sold at different prices, as well as intertemporal price discrimination and peak load pricing during certain days, which all affect demand. (See Courty and Pagliero, 2013 for a highly interesting survey and application of price discrimination by rock singers.)

The performing arts are prone to the superstar phenomenon, which is difficult to study empirically, since talent can hardly be measured and has to be circumvented by other measures.

Cultural Heritage, Where Do We Go

Forty-five thousand monuments are listed in France, and this number is increasing every year, without any legal possibility to drop a monument once it is listed. In the United Kingdom, there are 40 000 scheduled monuments and sites and 500 000 listed buildings. Maintaining this heritage obviously implies costs, and these costs are increasing. The number of specialists who are able to reconstruct and restore these sites is dwindling, the materials needed are becoming rare and often expensive to extract, and monuments deteriorate at an increasing rate, since they are subject to pollution and visited more often (Benhamou, 2000: p. 58). The decision to list heritage sites less often will have to be made, and perhaps also the decision to drop monuments and allow their demolition. Property rights

may have to be redefined to induce private owners to care for their properties, and tools, such as contingent valuation, polls, or even referenda may be needed to elicit preferences and help decision makers.

The number of museums has also increased dramatically during the past 20 years, and so have collections, generating serious constraints on exhibition space: 80–90% of the collections are not shown (97% in the case of the Art Institute in Chicago). Though the International Council of Museums (ICOM) recommends that each museum should have a statement describing its collecting policy, many have no such written documentation. Why can't existing museums stop increasing their collections, and why is it that so many new museums are being born? Why is it that if curators are empowered with the possibility to buy works of art, it is made difficult (in the United States) if not impossible or unlawful (in Europe) for them to sell works, including the thousands of broken Greek vases that almost each museum holds? This would not only ease their financial situation but also reduce the incentive for illegal excavations and sales.

Should museums charge entrance fees? Curiously enough, the French, whose successive governments claim to have the largest budgets to support the arts, insist that museums should charge visitors and they do so, while free admission at the six British national museums, some of which currently charge, was introduced in April 2001. Some experiments are being run in French museums on the effect of charging and not charging entrance fees once every 4 weeks, on Sundays, but the evidence that this increases the number of visitors is scant. More serious econometric work is obviously needed in this area.

How would the management of museums be affected if the value of their collections were considered as fixed assets? How should museums (as well as many other cultural institutions) be evaluated? Their output can obviously not be measured by profits, or by the number of visitors, as has often been suggested and done. According to the ICOM definition, a museum "acquires, conserves, researches and communicates, and exhibits for the purpose of study, education and enjoyment, material evidence of people and their environment." This makes for an activity with multiple outputs and calls for using appropriate efficiency frontier methods to measure performance. (Detailed accounts faced by heritage policies are discussed by Towse (1997a), Schuster (1997), and Peacock and Rizzo (2008).)

The Cultural and Creative Industries

Cultural industries mainly produce 'multiples,' such as books (Though some books can be viewed as works of art. This is obviously the case for old manuscripts, but also for limited editions which become collectors' items.), records, movies, newspapers, and TV programs, and the value of the work is not conferred by its uniqueness or its scarcity. Like in other sectors, these industries are faced with globalization and follow the move to more concentration, both in terms of production and of distribution, which may open the road to more uniformity.

At issue are also (1) the public support to (and even the ownership by the state of) television and radio stations and, in some countries, newspapers, and the complex problems of (dis) information this may generate, (2) import quotas on cultural programs in a world which moves to free trade in all other industries, (3) the complex economic and legal copyright problems (Landes and Posner 2003; Towse 2008b) as well as those generated by the internet and what came to be called 'piracy,' though, as shown by Waldfogel (2011a,b), this has not affected the creativity of singers and composers. Protecting very concentrated industries such as the recording industry by tougher copyright laws does not necessarily increase consumers' welfare.

The terms 'cultural industries' has recently morphed into 'creative industries,' the title of Caves' (2000) important volume in which contract theory is used to illuminate the workings of the industry.

Concluding Remarks

We have covered the main issues that look more like a puzzle the many pieces of which have still to be assembled, but the subject is still young, and economics itself, though it is much older, is also an unassembled puzzle. Additionally, we are left with many unresolved questions. The economics of certification or authentication ('authentic' works versus copies, or fakes) is one of these. While many art philosophers maintain that this does not change the aesthetic qualities of a work, it definitely changes its price. The formation of values also raises the interesting issue of who are the agents endowed with the power to discriminate between good and bad art. What is the expertise of those who grant prizes and awards? Who would today award the 1959 Oscar for best movie to *Ben Hur* and forget about *Some Like it Hot* produced during the same year? See English (2005) and Ginsburgh and Weyers (2008) on prizes and competitions.

Why did blockbuster exhibitions or music, opera, and theater festivals become so numerous? Don't such events simply displace the public from more traditional venues? Much has been said on the rent-seeking behavior of those who organize such events, but little is known on the long-term effects on the behavior of those who attend. See Frey and Busenhart (1996) and Gergaud and Ginsburgh (2014).

The last question, which is also one of the most important ones, is how does culture affect the preferences of consumers. This is the subject of the important article by Stigler and Becker (1977), who were among the first to discuss changing tastes including addiction to culture in terms of a household production function and the stock of past consumption (of culture) and not consumption itself, appearing as argument in the utility function. Addiction (if positive) should enhance the role of education to culture. More of it would certainly lead to more participation in cultural activities and, therefore, to less need for public support. It would also increase efficiency, since consumers would then have enough information to choose in a sovereign way, and we would have to accept the consequences to which this could lead.

I am not fully happy with the field since it is going in the direction of much more empirics than theory and more management and cultural policies than economics. There is little in terms developments that spilled over outside its own domain, as observed 13 years ago by Blaug (2001). He adds "that [this

was] perhaps asking too much of a subject no older than 30 years?" We are unfortunately still in the same situation 13 years later.

Art and Socialisation

Abstract

This article discusses the impact of arts socialization on participation in arts. Arts participation is characterized by large social inequalities. We focus on early arts socialization by parents and later socialization at school and discuss two models that explain the link between social inequalities and arts socialization: the cultural reproduction model and the cultural mobility model. The models differ in the importance they attach to early socialization by the parents and later socialization in schools. In addition, we discuss the status theory and the information theory, which explain effects of arts socialization, respectively, by social context and cognitive capacities. Finally, we review some relevant empirical studies, noting their substantive findings and/or methodological shortcomings.

Introduction

Visiting museums, going to the theater, attending a concert, or reading a novel are all expressions of personal taste. However, they are also reflective of a person's position in society, a connection that is much more salient in the arts than in any other lifestyle domain (Bourdieu, 1984[1979]). Those who enjoy the arts are often better educated and were exposed to the arts at home. The strong influences of both family and education on arts participation suggest that early socialization is decisive: cultural preferences start early, with parents and schools acting as socializing agents. Research shows that these effects endure over the life cycle and may even become stronger in early adulthood. This article examines the relative impact of family and education as socializing agents on participation in the arts in early and later life.

Socialization is the process by which skills, knowledge, values, and habits prevalent in a particular social group are conveyed to newcomers who become part of that group, either as the next generation or as new members. Parents are responsible for the socialization processes of early childhood, whereas school and peer groups gain importance as the child grows older. In adulthood, socialization processes continue, e.g., in friendship networks, in partner relationships, and at the workplace.

Studies on arts socialization distinguish between primary socialization, i.e., early socialization by parents, and secondary socialization, outside the family of origin, starting somewhat later in life, particularly in education (De Jager, 1967). Socialization processes are partly intentional, to the extent that parents or teachers overtly encourage and correct children's attitudes and behavior, and partly unintentional, to the extent that children observe (or model) others (Bandura, 1969).

Research on social stratification and social mobility identifies participation in the arts as a primary component of 'cultural capital' (Bourdieu and Passeron, 1990[1977]) that pays off in both educational and occupational attainment. The literature proposes two models explaining how people acquire such cultural capital (DiMaggio, 1982): the cultural reproduction model and the cultural mobility model (see **Figure 1**). The cultural reproduction model holds that family arts socialization induces arts participation and is used by high-status parents to ensure a similar social position for their offspring. The cultural mobility model implies that school and peers can compensate for a lack of cultural resources at home, and arts participation can become a means of upward mobility.

On the effective ingredients of arts socialization, two theories can be identified. Status theory considers arts participation to be a normatively driven activity and stresses the social context as the operative part of socialization. By way of

Figure 1 Cultural reproduction model and cultural mobility model.

contrast, information theory views arts participation as a cognitive activity and emphasizes instruction and the transmission of knowledge on art as crucial to socialization.

In what follows, we briefly discuss the cultural reproduction model and the cultural mobility model, before turning to basic theories of arts socialization. We then summarize the empirical evidence.

Cultural Reproduction and Cultural Mobility

The cultural reproduction model and the cultural mobility model both stress the social advantages that accrue from cultural capital, but they disagree on how it is acquired: the former says it comes from parents (Bourdieu and Passeron, 1990[1977]), and the latter points to influences outside the parental home (DiMaggio, 1982). In other words, they offer different views on the relative importance of primary socialization by the parents and secondary socialization outside the family of origin, especially in education.

Cultural Reproduction Model (Bourdieu)

The cultural reproduction model states that arts socialization is a key strategy by which parents pass their social position onto their children. In this view, arts socialization is exclusively provided by parents and is only effective when acquired at home. Bourdieu et al. (1991[1969]: 64–70) argue that the capabilities and attitudes needed to appreciate the fine distinctions that characterize art and art forms can only be acquired at home. In their view, appreciating art requires a process of gradual familiarization and regular exposure over a long period, and only parents can provide this. Children of culturally active parents, without being explicitly taught about art, regularly come into contact with various art forms and develop the attitude and knowledge required for appreciation. Bourdieu et al. (1991[1969]) argue that schools generally cannot provide the extensive and uninterrupted exposure necessary to develop a lasting appreciation of art. Schools may take their students to artistic events (plays, exhibits, etc.) and help them to appreciate certain works of art (books, paintings, etc.), but this can never be as extensive as the exposure provided at home. Dutch sociologist De Jager (1967) offers similar arguments, claiming that the impact of family socialization is much stronger; the influence of other socializing agents is only temporary and not comparable to the persistent and overriding parental influence.

According to cultural reproduction theory (Bourdieu and Passeron, 1990[1977]), schools reproduce existing social and cultural inequalities. A school diploma represents a particular status culture that corresponds to the graduating students' social positions; the prestige of a school varies according to the students it attracts and the value of the diplomas it grants (Bourdieu, 1984[1979]: 25–26). In addition, teachers evaluate students not only by their cognitive abilities, but also by their fitness for future positions. Students who are familiar with culture and art are assessed as suitable for higher status destinations and are favored by teachers who belong to these status groups themselves. As a result, students from culturally active families do better in school. The process is reinforced by the students who, in a process of anticipatory socialization (Roe, 1992), adapt their aspirations to accord with the social positions they are expected to assume.

According to the cultural reproduction model depicted in **Figure 1**, arts socialization in the parental family strongly affects arts participation in adult life (a) In addition, the model assumes that children who have been raised with art go to more prestigious schools where arts are valued and mix with peers from similar family backgrounds (b) The school environment may offer independent arts socialization, but its effects are minor (c) if arts socialization in school is at all helpful, it will help those who have already been familiarized with art at home, simply strengthening the effects of parental arts socialization (d) Arts socialization at school does not fill a gap for those children who have not acquired cultural capital in the parental family.

Cultural Mobility Model (DiMaggio)

A contrasting idea on the formation of cultural capital is offered by the cultural mobility model (DiMaggio, 1982). When DiMaggio (1982) empirically tested Bourdieu's cultural reproduction model in US high schools by examining whether students' cultural capital affected their grades, he found that over and above students' cognitive abilities, teachers gave higher grades to those with more cultural capital. Interestingly, DiMaggio also found that students' cultural capital was not or hardly related to the social position of their parents. He termed this latter finding cultural mobility.

While the cultural mobility model shown in **Figure 1** acknowledges the role of cultural preferences in status attainment processes and does not deny the importance of the family in the formation of cultural capital (a) it assumes there are ample opportunities to acquire cultural capital outside the family, and these are open to lower status groups (b) It further assumes that cultural capital gained this way will be as effective as cultural capital gained at home (c) In other words, students who are not raised with art in their family of origin may find other opportunities to acquire cultural capital, particularly at school (DiMaggio, 1982; DiMaggio and Useem, 1978). Opportunities include the school curriculum, extracurricular activities, and peer groups. As cultural capital is valued irrespective of how it is acquired, it can be used as a strategy to achieve upward mobility. Ambitious students from lower status families will be able to bring their cultural preferences and arts participation to a higher level to accord with their desired social positions. In such cases, schools compensate for a lack of parental influence (d).

Cultural Reproduction vs Cultural Mobility

Both models indicate the importance of participation in the arts for status achievement. Sensitivity to the arts is a key issue, especially for those lacking a high-status background. Particularly interesting in this respect, not just for academics and educators, but also for policy makers, is the role of the school and the extent to which the school offers students opportunities to learn about the arts, thereby increasing their chances of entering higher status groups.

Two Mechanisms of Arts Socialization: Status Motives and Cultural Competence

While the cultural reproduction model and the cultural mobility model problematize the relative influence of family vs school (and other social contexts), they do not focus on the underlying mechanisms of socialization. Socialization processes inherent to the formation of cultural capital include the transmission of social norms and cultural competence. On the question which of the two is more effective in furthering arts participation, two competing theories have been proposed (Ganzeboom, 1982): status theory and information theory.

Status theory assumes that arts participation is normatively driven; therefore, a student's various social contexts (family, school, peer group), and their respective norms are the operative parts of the socialization process. According to information theory, however, arts participation is a cognitive activity and the transmission of knowledge (i.e., information transfer) is the crucial part of socialization. It also points to generic cognitive capabilities that are present before parental and/or school socialization starts. The literature on the effects of cultural capital on educational attainment proposes a similar distinction in mechanisms of arts socialization by differentiating between reading, assumed to be driven entirely by cognitive capacities, and other, more socially driven disciplines (Crook, 1997; De Graaf, 1986; De Graaf et al., 2000; De Graaf and De Graaf, 2002; Evans et al., 2010; Kingston, 2001).

Status Theory

Cultural capital is defined by Lamont and Lareau (1988: 156) as consisting of "institutionalized, i.e., widely shared, high status cultural signals (attitudes, preferences, formal knowledge, behaviors, goods and credentials) used for social and cultural exclusion." Status theory (Ganzeboom, 1982) emphasizes that arts participation, one aspect of cultural capital, provides a visible demarcation in the social hierarchy, and is driven by a desire to maintain these boundaries (Bourdieu, 1984[1979]). It expresses membership in higher social status groups and can be used to assess the suitability of newcomers to enter these groups. Thus, it maintains the boundaries between social status groups.

According to status theory, arts socialization includes learning definitions of correct taste or what is and what is not appropriate, in short, the social norms of arts consumption. Status theory assumes that social contexts in which the arts are valued and where arts participation is the norm will stimulate participation among their members. New members will gradually develop the tastes and behaviors that match the social group. Normative arts socialization starts in the parental family, but in a later stage, other social contexts – school, peers – add relevant socialization contexts. Status theory works for both the cultural reproduction and cultural mobility models: for those already socialized into the arts by the family, socialization at school accords with the family background; for others, introduction to the arts will start at school or in the peer group. The status mechanism can be reconciled with both cultural reproduction and cultural mobility. The two models differ in the relative importance they attach to early and later social contexts.

An important implication of status theory bears on participation in various art disciplines. To the extent that arts participation represents a single status culture, participation will occur in several art disciplines at the same time (DiMaggio, 1982: 191–192). In other words, normative arts socialization and its effects will be diffuse and involve multiple disciplines, as long as they procure prestige in the social status group.

Information Theory

Information theory (Ganzeboom, 1982, 1984) emphasizes that the arts constitute complex sources of information and their enjoyment requires a considerable amount of cognitive capacity. Those who lack these capacities will experience art as difficult, making them likely to refrain from arts participation. An enhanced knowledge of art that leads to greater participation results from both intended and unintended instructions, and both acquired knowledge and generic cognitive abilities play a role. Information theory does not make predictions on the effects of the timing of arts instruction (i.e., in early or later childhood, or in adolescence), but as noted above, the cultural reproduction and cultural mobility models offer contrasting accounts of the value of arts instruction in childhood (by parents) and adolescence (by school and peers).

Although knowledge of art may be transferable from one art discipline to another (Bourdieu et al., 1991[1969]), to the extent that art socialization concerns the transfer of specialized knowledge, it will particularly affect the art discipline in which the instruction takes place. For the most part, discipline-specific arts lessons will lead to separate art publics. Information theory also predicts that the effects of arts socialization will be strongest for art practices for which more artistic competence is a prerequisite, hence, the more complex disciplines.

Finally, information theory asserts that generic cognitive abilities enhance the capacity to process the complexity of art works. Assuming these generic cognitive abilities are present early in life, this implies that differences in arts participation are due to differences in already existing cognitive capacities. This has important implications for assessing the empirical evidence. Because measures for generic cognitive abilities are scarce in research (see below), these abilities are generally represented by educational level. An effect of educational level, therefore, cannot directly be interpreted as an effect of arts socialization during schooling.

To the extent that generic cognitive abilities affect arts participation, there will be overlap between art forms; however, assuming that reading is a more cognitive activity, the effects of generic cognitive abilities will be stronger for reading.

Methodological Challenges

Empirical research on the total and relative impact of family and school as socializing agents in arts participation faces many challenges. Ideally, determining the causal effects of arts socialization requires (quasi-)experimental designs, but their use is limited to assessing the effects of specific arts instruction programs. In practice, the effects of arts socialization can only be studied through observational survey designs in which respondents are asked to report on the issues of interest.

Information is collected on respondents' current arts participation and their education, but not always on the arts socialization they have experienced in different social contexts. For instance, the number of studies that include explicit measures of parents' arts socialization is limited (Sullivan, 2011: 197).

A first serious pitfall of arts socialization research is that education effects are attributed to normative socialization and instruction in schools, but they may simply reflect the filtering effect of education. In modern and meritocratic societies, one role of education is to sort students by their cognitive capacities. The differences found in arts participation between higher and lower educated persons in studies that only include education as a variable cannot be attributed to arts socialization by school. At best, education may reflect arts socialization if a measure of generic cognitive capacities is controlled, and measures of generic capacities, in turn, capture only part of the educational filtering effect.

Second, studies that include information on school socialization practices may suffer from selection bias: arts socialization provided by school in optional courses may be dependent on family background or prior interest in the arts. Therefore, to determine the effects of arts socialization in school, parental socialization practices should be controlled, or at least parents' level of education; otherwise, the effects of the school's arts socialization could be due to the parents' socialization. The problem of selection bias does not apply to the effect of parental arts socialization, because it can be safely assumed that parental participation represents independent family socialization, once education and parental education are controlled. Causality in observational research can be identified by applying longitudinal designs comparing respondents over time, before and after exposure to socialization contexts (Nagel et al., 2010). Such panel designs allow for controlling prior arts participation and assessing the additional influence of secondary socialization.

Third, an approach that uses only measures of arts socialization to assess the relative influence of primary and secondary socialization contexts remains necessarily incomplete. Ideally, to estimate the total and relative impact of family and education, all influences that children have been exposed to by the family and by school should be taken into account. Such total effects of family and school contexts can be established in multilevel models by comparing the degree of resemblance in arts participation between students and their siblings (family context) and their schoolmates (education context). However, it is virtually impossible to combine comparisons between siblings and schoolmates simultaneously in a single design. The family context is more or less stable, whereas children may experience several school and class contexts.

Fourth, most measurement of early socialization occurs retrospectively and by proxy and may be vulnerable to both random and systematic measurement error; as such, reports may contain too much noise or be biased toward current practices (De Vries and De Graaf, 2008). Researchers have occasionally been successful in obtaining nonproxy measures, i.e., by obtaining reports of the socializing agents themselves.

Fifth, the effects of parents' arts participation controlled for education are often interpreted as the normative dimension of arts socialization, while the effects of education controlled for parents' socialization are considered to represent the effect of cognitive capacities. But part of the arts socialization by parents could be the transmission of cultural competence, and part of the effect of education could be due to social norms on arts participation. One way to learn more about the active ingredients in family and school socialization would be to include explicit measures of social norms or cultural competence. However, we do not know of any studies with such measures that can safely be assumed to be causally prior to actual arts participation. Another way to identify the active ingredients of arts socialization is to differentiate among various art forms in the degree to which they signal high status and cognitive capacity, and to see if the effects are stronger for one or the other.

Empirical Evidence

Much of the existing empirical research is from the Netherlands, where a strong research tradition has developed, beginning with the work of Wippler (1968) and De Jager (1967) in the 1960s. This tradition continued with Ganzeboom (1984), De Graaf (1987), Kraaykamp (1993), and Van Eijck (1996), along with a number of other dissertation projects. As a consequence, in the Netherlands, many data sets on cultural participation are available, including arts socialization by parents and school. (Many of these are accessible via the Dutch data archive www.dans.knaw.nl.)

Family Socialization

Without exception, studies that include parents' arts participation report moderately strong effects. Typically, parents' arts consumption is measured by adult respondents' retrospective reports on their own parents' arts participation while they were growing up (usually between 12 and 16 years of age). These studies find that when education is controlled, parents' cultural participation is a strong determinant of the children's arts participation, with standardized effects around .30 years (e.g., Kraaykamp and Nieuwbeerta, 2000; Kraaykamp and Van Eijck, 2010; Yaish and Katz-Gerro, 2012). Slightly stronger effects are reported in studies that control random measurement error (De Graaf and De Graaf, 1988; Ganzeboom, 1982) and systematic measurement error (De Vries and De Graaf, 2008).

Strong resemblances between parents' and children's contemporaneous arts participation are found in many studies (Crook, 1997; Damen et al., 2010; Jæger, 2009; Sullivan, 2001; Van Wel et al., 2006; Willekens and Lievens, 2014), albeit to a lesser extent when parents report on their arts participation independently (Nagel, 2010). Interestingly, Van Wel et al. (2006) and Willekens and Lievens (2014) show that a mother's influence is generally stronger than a father's influence. Van Wel et al. (2006) also find that her influence is stronger on her daughters than on her sons. Although arts participation in adolescence is part of the socialization process itself, the contemporaneous effects of family imply that cultural careers start and take decisive turns quite early.

Similar strong associations are found between parents' literary reading during the socialization period and later in life (Kraaykamp, 2003; Notten, 2011). Research using independent measures of parents' socialization also finds that parents'

reading levels affect the reading of prestigious books in adulthood (Verboord and Van Rees, 2003). Nagel and Verboord (2012) find that reading frequency among adolescents and young adults is strongly determined by parental reading and secondary education. In fact, the effects of parents' reading frequency increase a little in this period.

In addition to the effects of parental example (unintentional learning), Kraaykamp (2003) and Notten (2011) find effects for deliberate parental strategies to stimulate children's literary reading, such as reading to them, giving them books as presents, and showing interest in their reading. However, Notten (2011: 102) concludes that direct imitation is the main process by which parents transmit their preferences in reading and television to their children. Verboord and Van Rees (2003: 295) do not find additional effects of parents' reading socialization activities on the reading level of their children. Lack of effect of explicit instruction is confirmed by Kraaykamp and Dijkstra (1999) who, in a sample of book readers, find no effects of parents' socialization activities on reading level when the educational level is taken into account. By contrast, Verboord (2005) finds effects of parental socialization practices and attitudes on the frequency of reading, and Tepper (2000) finds positive effects of parental encouragement on reading fiction in the United States.

The above studies assess the impact of parental arts socialization by explicit measures of parents' arts participation or socialization practices, but parents may affect their children's interest in arts in other ways. Total effects of family of origin can be estimated by studying sibling resemblance in arts participation. The few studies that study arts participation by using a sibling design generally report stronger influences of families (Ganzeboom and De Graaf, 1991; Van Eijck, 1997; Nagel and Ganzeboom, 2002; Willekens and Lievens, 2014) than those using measured parental characteristics. Van Eijck (1997: 215) concludes that shared family characteristics account for 37% of the variance in the cultural consumption of adult siblings. Van Eijck (1997: 221) infers that parents' cultural resources 'are the strongest determinant of siblings' cultural participation,' more important than education.

Nagel and Ganzeboom (2002) find 38% explained sibling variance in a sample of former secondary school students aged 25–35 years; when the secondary school context is controlled, this figure drops to 28%, still far above the findings when explicit socialization measures are used. They also find that the family effects are rather stable in the period from adolescence to adulthood. Although these total effects include other shared family characteristics besides arts socialization practices (i.e., shared general cognitive ability), parents' arts participation explains a large part of these total effects; the stability in arts participation is mainly caused by family of origin. While the effects of parents' arts socialization are stable between adolescence and early adulthood, however, the effects of education increase in that period. By way of contrast, in a Belgian study, Vander Stichele and Laermans (2007) find no effects of cultural participation at age 12 or 14 years on later arts participation.

To summarize, many studies report moderately to strong effects of parental socialization on a person's participation in the arts, both in adolescence and in adulthood. Studies of reading suggest that the example set by parents is more important than their intentional socialization practices. The available evidence also suggests that the family influence starts early in life and remains stable afterward. The strong effects of parental socialization fit both the cultural reproduction and the cultural mobility model; both predict that arts socialization by parents has an early and lasting effect on children's arts participation. However, the stability of the effects of parents' socialization (strong in adolescence and in adulthood) favors the cultural reproduction model.

School Socialization

The school as a socialization context encompasses the level of education (lower/higher primary, secondary, and tertiary), the curriculum (including school-based arts instruction), the school climate (extracurricular activities), and the peer group. Of these, only the effects of arts education and the level of education have been researched systematically.

Research has found that parents' arts participation, next to their education, affects their children's type of schooling, more so in the early school career (Aschaffenburg and Maas, 1997). Moreover, enrollment in school-based arts education turns out to be highly affected by prior interests in the arts and by parents' arts participation (Nagel et al., 1997). Finally, peers in school classes select each other partly because of similarity in their parents' arts participation (Nagel et al., 2011). Thus, parental and school contexts are often at least partly aligned, and to assess the effects of socialization at school, it is imperative to control the effects of parental arts socialization.

Arts Education

Using the US Survey on Public Participation in the Arts (SPPA) 1992, Kracman (1996) finds that school-based arts education affects museum visiting and performing arts attendance later in life. The effects arise over and above those of the mother's and father's education and the educational level of the respondent, but the research is entirely based on retrospective reports. For the 2008 SPPA survey, Christin (2012) also reports a positive effect of art lessons in childhood on a broad spectrum of highbrow culture. However, as both analyses lack parents' arts socialization practices as a control, the effect of arts education may have been overestimated.

Nagel et al. (1997) use a prospective design in which enrollment in a specific arts examination program was measured by secondary school archival records. Although enrollment in this program was found to be selective according to parental socialization, prior arts participation, and humanities in the curriculum, it turned out that 10–20 years later in the life course, former secondary school students who had taken an exam in visual arts and music more often participated in visual arts and music (attendance at events and participation at home) than their schoolmates who graduated from the same schools but did not take these arts exams. Overall, the effects of arts education are smaller than the combined effects of prior and parental arts participation, but larger than the effect of the level of secondary education. The effects occur mainly within disciplines: visual art education enhances museum attendance; music affects concert attendance. Two other studies on the same data

reveal that the effects are smaller if arts participation is restricted to arts attendance (Nagel, 2004) or when a composite measure of different art disciplines is used (Nagel and Ganzeboom, 2002). Nagel (2004) shows that the effects of arts education on arts attendance are highest in young adulthood and then fade away.

Nagel et al. (2010) evaluate an arts course in the Netherlands that compels secondary school students (age 15–16 years) to visit 6–10 arts events in several art disciplines. Two to six years after completion of the course there were no differences in arts participation between students who had been enrolled in the course and a previous cohort who had not. Damen (2010:31) characterizes the course as 'too little, too late,' pointing at the multidisciplinary character of the arts course and the timing (ages 15–16 years) in the curriculum.

With respect to reading literary works, positive effects of school socialization practices have been reported. Kraaykamp (2003) finds that literary reading is stronger among those who took more humanities courses in the secondary school curriculum and who reported a stronger interest in culture when they were in secondary school. In a sample of book readers, Kraaykamp and Dijkstra (1999) find (equally) positive effects of school stimulation on the complexity and literary prestige of reading preferences. Although measures of parental socialization practices are taken into account in these studies, the measure of school socialization will probably include some self-selection effects. Verboord and Van Rees (2003) find that the time spent at secondary school on literature enhances the reading of prestigious books in adulthood, over and above parental socialization. In this study, the direct effects of school socialization are comparable in size to the direct effects of parental socialization and secondary education (but as the model comprises intervening variables, the relative sizes of the total effects remain unclear). Verboord (2005) finds that reading frequency is not affected by the amount of literary education in secondary school, but by the didactic approach of the teacher (student-centered teaching methods enhance reading; teacher-centered methods have the opposite effect).

To summarize, art lessons in secondary school may enhance arts participation later in life, but the effects are weak and seem somewhat more convincing for reading than for arts attendance. The effects of art lessons appear to be confined to the same arts discipline in which instruction took place, suggesting that the active ingredient of art socialization by school is the specific cultural competence.

General Education

Without exception, studies of educational effects on arts participation find strong associations with the level of education (DiMaggio and Useem, 1978; Kracman, 1996; Christin, 2012), but it is important to control for parents' arts socialization and educational filtering.

Studies including parents' arts participation report effects of education that are roughly equivalent to the effects of parents' socialization: while some report slightly larger effects of parents' arts participation (Kraaykamp and Nieuwbeerta, 2000), others find somewhat stronger effects of education (De Graaf and De Graaf, 1988; De Vries and De Graaf, 2008; Kraaykamp and Van Eijck, 2010; Yaish and Katz-Gerro, 2012). Still, the level of schooling may largely represent cognitive abilities; thus, the effect of educational level cannot be interpreted as evidence of the effect of arts socialization at school. One way to overcome this problem is to include a measure of cognitive capacities. Unfortunately, survey data sets rarely contain such a measure.

Another approach to overcome selection problems is to use dynamic designs that compare arts participation before and after enrollment in education. For example, Nagel and Ganzeboom (2002) find that the effects of final attained education (over and above secondary schooling) are not yet present in adolescence, but do appear around the age of 30 years. Apparently, the effect of final education rises during the life course and can be interpreted as the consequence of schooling. Other studies of adolescents corroborate the finding that the short-term effects of educational level are relatively small compared to the effects of education in adulthood (Van Wel et al., 2006). Nagel (2010) finds that in the period from adolescence to adulthood, the effects of education partly exist at the beginning of adolescence and partly increase as the educational career progresses.

Nagel and Verboord (2012) assert that this does not hold for reading. Reading frequency varies more strongly with secondary education than with parental arts socialization, but the effects of secondary education are transitory and probably have to be attributed to actual school socialization practices. They say there are no additional school effects on reading frequency over and above those already existing early in adolescence (at 14 years of age).

Daenekindt and Roose (2013: 321) differentiate between private and public cultural participation. They find that cultural participation is determined more by attained education than by the parents' education, more so in public participation (arts attendance) than private participation (media use). Although the larger effect of attained education could be due to educational filtering, the stronger effect on public than on private arts participation points to 'social motives.'

To summarize, although the association of education with arts participation is comparable in size to that of parents' arts socialization, only part of it can be attributed to the school as a socialization context. Educational differences in arts participation in adolescence, prior to completion of the educational career, are most likely caused by generic cognitive abilities but may also result from former education or be signs of anticipatory socialization (Nagel, 2010).

Conclusions

When we look at the relative importance of cultural reproduction and cultural mobility processes, we derive the following conclusions from the empirical evidence.

First, there is a strong degree of intergenerational transmission of arts participation: parents' arts participation is a strong determinant of their offspring's arts participation. Their example (unintentional socialization) is especially important, not, or to a lesser extent, their intentional socialization practices. Differences in arts participation emerge early

in life: these are already present in adolescence and remain stable in adulthood.

The large effects of parental socialization fit both the cultural reproduction model and the cultural mobility model. The stability of the effects of parental socialization (strong in adolescence and adulthood) favors the cultural reproduction model, but these effects do not negate the cultural mobility model's contention that arts socialization outside the family can be equally effective. The differences between the models depend on the effects of education as a socialization context, as well as how the two contexts combine.

Although arts participation is strongly associated with education, drawing conclusions on the causal effects of education as a socialization context is difficult, as there are multiple selection problems in the available empirical evidence. To the extent that we can attribute the school socialization effects to school, there is limited evidence of cultural mobility. Arts instruction in school may enhance arts participation later in life, but the evidence is weak, albeit a bit more convincing for reading than arts attendance. The few studies that try to unravel the additional influence of schooling by using a dynamic design find additional influences of educational level on arts participation, suggesting that the education effects are not solely a matter of cognitive filtering.

While the results generally favor the cultural reproduction model over the cultural mobility model, future research should aim for more decisive conclusions on the tenability of either model. First, researchers should decompose the net effect of the level of education into its underlying mechanisms. This could be done by including (independent) measures of generic cognitive abilities (in childhood) and measures of the mechanisms of schooling, not only of arts instruction, but also of the social context, i.e., the social composition of the school and the peer groups in the classroom. Second, to differentiate between the status and information mechanisms, more detailed information should be collected on arts that differ in their requirement of cognitive abilities and their status-enhancing qualities. Finally, instrumental variables (i.e., effects of socialization that affect arts participation exclusively via education) should be used to explicitly model intervening variables and examine to what extent education enhances cultural competence or status motives. Such econometric designs have not yet been applied in the research literature on art socialization.

Art, Anthropological Aspects of

Nelson Graburn, University of California, Berkeley, CA, USA

Abstract

Anthropologists assume art is a human universal, but have had to struggle with the cross-cultural identification of art, either by finding common forms and practices, e.g., painting, sculpture, and dance, or by exploring the aesthetic locus in each cultural system. All humans enjoy aesthetic appreciation, but their visual, aural, tactile, olfactory, and sensory preferences vary from place to place and over time. Anthropologists have examined the meaning of arts, in their psychological or psychoanalytic aspects and emotional power, as semiotic media of communication like language and signaling systems, or by examining their sociopolitical agency in guiding human relationships. Arts like other local practices have experienced cross-cultural exchange, colonization, and globalization. They have evolved both as symbols of specific ethnic identities, and as commercial and tourist arts. Crossing boundaries subjects arts to different audiences who make different interpretations, and meanings may be manipulated for power or commerce by mediators such as traders, anthropologists, and critics. As trade and travel erase barriers, artists of formerly separate peoples encounter metropolitan practices such as art school education, art galleries and museums, and the thriving and competitive mainstream art world. Many creatively enter that world while endeavoring to maintain ethnic distinctiveness, so that for instance, British, Inuit, Japanese, Spanish, and Maori arts are circulated and exhibited by the same or similar institutions. The contemporary world of dissolving boundaries, often called postmodernity, has allowed many practices formerly segregated as crafts, often made by women, to enter these same circuits and institutions; metropolitan artists have appropriated features of non-Western arts as their own, as non-Western artists take up metropolitan practices. There is a convergence as artists now engage in ethnographic research, and anthropologists emphasize the poetic (rather than the analytical) power of their works. Art historians emphasize the personal and contextual in art production while anthropologists extend their gaze at the metropolitan and global art world.

The term 'art' has several meanings, all having to do with the performance and products of human skills, associated with aesthetic (rather than functional, sacred, or scientific) qualities, appealing to the human senses. Art can appeal to a single sense, e.g., easel painting, or to multiple senses, e.g., ritual dances (vision, kinesthetic, sound). This article focuses on the visual arts rather than song, music, or dance.

The Term 'Art'

The meaning of 'art,' from the Latin *ars*, *artis* (skill), has changed over time, reflecting technological and social contexts. In English, 'art' is often twinned with 'craft' from the Germanic *kraft* ('skill, cunning' in English, since AD 850). After the Norman Conquest and the Renaissance, 'craft' became associated with manual skills and lower class occupations, and 'art,' from the French *art*, with the conquerors and the Church, hence with learned practices such as mathematics, rhetoric, logic, and grammar (as in Master of Arts).

In Enlightenment Europe, the meaning of 'art' changed again, becoming a synonym for *'beaux arts*,' a set of primarily expressive skills entertaining to the senses but with few practical aims. These arts were the enjoyment of the wealthy, educated classes whose tastes brought into being nonecclesiastical forms such as opera, symphonic music, figurative painting, and choreographed dance (and later ballet). Once detached from 'bread-and-butter' issues, art was justified as a superior expression of the human soul, whose practitioners embodied inner genius and were owed freedom of expression.

Many aesthetic practices of the unschooled members of European populations: folk song, dance, and handicrafts, and of women: quilting, lullabies, and sewing, were not considered arts. Others having both aesthetic and practical ends, architecture (versus building), landscape architecture (versus gardening), or cuisine (versus cooking), bestowed 'artist' status only on trained practitioners, usually men. These distinctions are fading with the postmodernist revaluations of many folk and vernacular practices as 'arts.'

The Challenge for Anthropologists

All these arts are embedded in the historical, social, and cultural structures of the Western world, and anthropologists find it difficult to identify 'art' in other societies. They have tackled the problem in two ways.

First, identify practices and products resembling Western arts, in form (appeal to certain senses) and in relation to context, e.g., religion, hierarchy, ritual. This was easy in the West's encounter with other complex civilizations (often archaeological), but difficult in more egalitarian nonliterate societies studied by early anthropology. In his *Primitive Art* (1955), Boas emphasized the universality of arts as skill-based productions of aesthetically valued forms

> When the technical treatment has attained a certain standard of excellence…such that certain typical forms [later identified as 'styles'] are produced, we call that process art…perfection is essentially an aesthetic judgement…[but] we cannot tell just where the aesthetic attitude sets in.
>
> 1955: 10

He added, "the twofold source of artistic effect, the one based on form alone, the other on ideas associated with form"

(1955: 13). Presumably the former would be aesthetic universals and the latter culturally specific, but Boas admits that other authors claim that all arts iconically represent something.

For Maquet (1979), all societies have aesthetic foci, where excellence is judged by the senses. But 'art' comprises only those productions that circulate within the metropolitan 'art world' (Becker, 1982), and 'primitive art' only exists in the galleries and homes of Western societies. Maquet, following Malraux (1967), posited that Arts are created two ways (1) by destination, made by self-conscious 'artists' for the art world and (2) by metamorphosis, produced either in the past or elsewhere, outside the art world. For instance, eighteenth-century quilts were not considered art until recently, and contemporary Dogon granary doors made for use in West Africa, only become 'art' when imported to the West. The current globalization of commodities makes Maquet's suggestion cogent for almost everything that would be 'art' by Boas' definition.

Meaning, the Content of Art

After the demise of nineteenth-century museum-based anthropology, with its evolutionary and diffusionary overtones, anthropological approaches to art since the 1960s have been concerned with the mechanisms and nature of the messages carried by art. They have drawn upon either psychology or linguistics, i.e., semiotics, reflecting functionalist and structuralist modes of anthropology.

Psychological Approaches

Psychoanalytic approaches treated art, like dreams and myths, as expressions of the subconscious, translated into forms acceptable to the conscious Ego. Most assume the universality of the Oedipus complex and the sublimation of aggression. Jungian approaches posit a universal set of archetypes, whose meanings are personally or locally adapted to solving problems.

Devereaux (1961) said that art expresses taboos in palatable, aestheticized forms. Taboos may be universal, e.g., incest, culturally specific, e.g., sex in puritanical society, or idiosyncratic (neurotic). Arts are admired locally when the taboos are cultural and are more widely when they speak to universal human problems. This 'aesthetics as alibi' approach also underlies the works of Margaret Mead, Bateson, Scheiffelin, and to some extent Kardiner.

Fischer (1961), following Wallace and Barry, proposed that artists sense how their patrons receive satisfactions to needs generated by local sociopsychological contexts: the latent (nonrepresentational) content of art, the 'style,' presents aestheticized versions of social fantasies giving security or pleasure. For instance, symmetrical designs with repetitive simple elements characterize the arts of egalitarian societies, whereas the arts of complex hierarchical societies present enclosed asymmetrical designs integrating disparate elements. He also found that preferences for the curvilinear reflected male security and fantasizing about females. Tielhet (1978) suggested that the equivocal role of women artists in nonliterate societies resulted from men's jealousy of women's reproductive powers, compensating by control of artistic creativity and the hoarding of valuable materials.

Linguistic Approaches

Art, like language, is a communicative form, using a medium that carries a coded message understood by both creator and audience. Forge claimed that for the Sepik peoples, visual art could be read directly, but not reduced to words. In contrast, Munn (1973) showed Australian Walbiri painting consists of a number of iconic but polyvalent elements, combined in sentencelike structures, to make symbolic statements about dream-time ancestors, often suggesting speech.

Levi-Strauss (1966) posits that "art lies halfway between scientific knowledge and mythical and magical thought … midway between design [the scientist builds structures from first principles] and anecdote [the *bricoleur* makes things from the 'debris of past events'] … The aesthetic emotion is the result of this union between the structural order and the order of events." Other structuralist analyses, such as Adams (1969) on Sumbanese textiles, reveal underlying systems of meanings interpreted locally.

For Bloch (1974), relations between aesthetics and emotion may be summarized "You cannot argue with a song!" He makes the analogy: phatic/illocutionary speech is to ritual/art as discursive/propositional speech is to secular behavior and mundane expression. Formal mechanisms, e.g., repetition, symmetries, limited range of elements, fixed sequences, archaic images, give the authorities who control ritual, rhetoric, and the arts power over those enculturated to these patterns.

Sociopolitical Approaches

Social anthropologists have stressed the functions of art in maintaining the social. Turner (1967) showed how Ndembu political rites use normative and naturalistic symbols and colors to structure the event and foster *communitas* among the participants, and Biebuyck (1973) demonstrated how human and animal figurines recall proverbs, functioning to train initiates in the Lega *bwami* cult. Gell (1996) asserts that anthropologists wrongly focused on aesthetics and on relationships between formal style and other cultural characteristics, because (1) 'art' is not always about aesthetics and (2) the expression of a culturally specific aesthetic system is not the function of art objects. Art is created to function in social relations to do something, i.e., it has agency, and art objects can serve as substitutes for social persons. In the West, art serves class and power interests, in gender exclusion (Nochlin, 1971) and the maintenance of social hierarchies (Bourdieu, 1984). Graburn (2005) went beyond Gell's original scope by extending his analytical framework to commercial ethnic arts.

Aesthetics, Ethnoaesthetics, and Universals

Little is understood yet about aesthetic universals. A number of anthropologists have explicated the local, i.e., ethnoaesthetic systems of, e.g., the Yoruba (Thompson, 1973), the Kilenge (Dark, 1974), and the Inuit (Graburn, 1973, 2005). Some have tried inconclusively to test the cross-cultural nature of aesthetic taste by, for instance, showing photographs of art objects both

to their non-Western makers and to Western students of art (Child and Siroto, 1965). However, Graburn (1978, 2001) drawing on the work of Salvador (1976) among the Kuna, was among the first to use a test exhibit of the actual art objects in comparing Native (Inuit) and Euro-American preferences. Other approaches drawing on Wittgenstein's philosophical work and other works on Paleolithic and ethnographic arts (Conkey, 1995; Marshack, 1972) show promise; there are possibilities that underlying aesthetic universals are related to neuro-ocular phosphenes and the structure of the brain itself (Onians, 2008).

Art in the Contemporary World

Ethnic and Tourist Arts

Early anthropological analyses focused on embedded 'authentic, traditional' arts, known as 'primitive' or 'non-Western' arts (Gerbrands, 1957). In *Ethnic and Tourist Arts* (1976), Graburn examined their entry into the 'World Art System,' (Becker, 1982) looking at the primary audience (locals or the external market) and the sources of aesthetic forms (traditional, external models, or novelties). Others have focused on such arts, in Africa and the Americas where traditional 'primitive' arts were found, and in literate civilizations, which have fallen under Western influences (Phillips, 1992). Questioning the historically contingent distinctions hybrid/purebred, Morphy (1992) revealed identical structural and aesthetic patterns underlying functional (locally directed) and commercial (market) Yirrkala bark paintings. Neich (1993) examined a colonial era (1870–1910) form of Maori figurative painting stylistically influenced by *pakeha* (white) culture but expressing Maori cosmology.

Cole (1985), Appadurai (1986), Clifford (1988), and Thomas (1991) have shown the historical depth and socio-cultural complexity of art production in colonial or post-colonial, often touristic, contexts. Dealers, curators, and tour directors may present historical artifacts as 'purebred' symbols of rich heritages, but practically everything in our ethnographic collections was acquired in colonial situations. They may be trade replicas or, like the carved arts of the Northwest Coast Indians of North America, they may have enlarged and proliferated with new tools and economic stimuli. Often, colonists both consumed and imitated contact arts, attempting to assume a new 'ethnic' identity by appropriating the culture of the conquered.

Recent works have focused less on the objects and more on the agency of the personnel of the art world. Ethnohistorical analyses: Cohodas (1997), Batkin (1987) and Phillips (1998), and ethnographic research (Steiner, 1995), reveal the complex activities of artists, intermediaries, and consumers. Artists may consciously work in a variety of styles, aiming at a number of consumer markets (Jules-Rosette, 1984), or they may themselves play the role of intermediaries.

When artists and consumers are culturally or geographically separated, mediating agents assume greater importance (Steiner, 1994). They not only transmit the physical art object from the producer to the consumer but also control the flow of information about its origin, age, meaning, and status as a commodity or a treasure (Appadurai, 1986). They also transmit back the demands and the ideology of the collectors, in terms of price, repeat orders, or information about form, content, color, and materials.

Artists dependent on the cross-cultural market are rarely socialized into its symbolic and aesthetic system, knowing little about the art world, or even 'art' itself. They live in a minefield of rules that they overstep at their peril, unless they assimilate into the 'art world' (Graburn, 1993). The Australian Aborigine watercolorist Namatjira painted successfully in the style of his white mentor, engendering both praise and jealous racism among the Australian public, leading to his downfall (Batty, 1963). Today's Third and Fourth World peoples have increasing exposure to mainstream arts and art materials. Many have attended art schools and assumed the burdens of (Western) art history and the ideological values of originality, artistic freedom, and individual creativity.

The separation of the art circuits for Native arts and mainstream (Euro-American) arts is eroding. Many Native artists work in genres of the metropolitan world art. The contents of their art may not be recognizable as 'ethnic,' possibly because white artists have appropriated so many ethnic motifs. When competing in the world market, Native artists signal their ethnicity through presentation of traditional content, inclusion of stereotypical motifs and color schemes; choice of title or use of a Native name (or 'tribal' designation with a nonethnic name); or the inclusion of written statements expressing a Native point of view (Sturtevant, 1986; Smith, 2009). Inclusions of non-Native contents, motifs, names, and titles may draw criticism or rejection by the market.

Ethnic artists are everywhere pressured to create arts conforming to the image desired by the mainstream market. Even the 'Magiciens de la Terre' (Martin, 1989), which exhibited 'world artists' in Paris, revealed by juxtaposition how the 'ethnic' artists were expected to create something stereotypically traditional, but the metropolitan (white) artists drew their motifs or materials from natural or cultural alterity (otherness) without limitation.

The Metropolitan Art World

Very few anthropologists have tackled the core institutions and activities of the metropolitan art world itself. Berlo (1992), Gerbrands (1957), Graburn (1976), Krech (1999), and Price (1991) have all examined how this art world has classified and examined non-Western arts. Myers, in his work on contemporary Australian aborigine dual purpose (sacred and commercial) arts, has best analyzed the Western art discourse about such arts (Marcus and Myers, 1995).

A number of excellent detailed ethnographies of contextualized contemporary arts in the globalizing world have followed Myers (2002a,b) who examined the complete set of events and transaction from the making of (Central Australian) Pintupi art to its exhibition of the highest realms of the metropolitan world. He showed that in order for the authentic meaning of the art to be transmitted to its final audience, a task undertaken by art historians and art critics for 'art by destination' (Maquet, 1979) produced in and for the metropolitan world, anthropologists have to serve as the mediators for they,

as exemplified by his book, have a thorough knowledge of the artists and the social and material circumstances of production. This is the antithesis of the (1) attitudes of the Cubists and others of a century before who only took inspiration from the visual forms of 'primitive' arts while disdaining the beliefs that lay behind them as well as (2) the transmission of misinformation in the sales pitches of contemporary African arts by 'runners' (middlemen, often Muslims) to Europe and North America (Steiner, 1991, 1994). Morphy confirmed the situation of 'Anthropology as a Mediating Discipline' (Morphy, 2007: 8) in his analysis of the comparable 'arts by metamorphosis' of the North Australian Yolngu. Adams working in Toraja, Indonesia, shows how art serves as 'an active ingredient in identity politics' (2006: 209) within the multicultural globalizing nation of Indonesia, and within the grasp – photographically for the many metropolitan tourists who witness but cannot purchase the complex and colorful rituals around the *tongkonan* funeral houses – and literally for the purchased or stolen – or faked – funeral figures that end up as 'arts of destination' in the galleries and homes of those tourists. Fair's comprehensive posthumous compendium on Alaska Native Arts (2006) is based on more than 20 years of intimate knowledge of the artists in their villages and in urban areas, first as a commercial collector and later a study of anthropology and art history. While nostalgic for a less threatening time of culture contact, the work contains no hesitation or excuses about the often commercial motivations of the Native artists nor purist longing for traditional or 'precontact' materials and techniques, treating them as artists with aesthetic and technical problems to solve trying to make a livelihood, much as did Inupiaq artist Ron Senungetuk, founder (in 1965) of the Alaska Native Arts Centers at the University of Alaska, Fairbanks. Jonaitis and Glass (2010), an anthropological art historian and an art historical anthropologist, have together written a complex account of the transformations of the Northwest Coast totem pole for ethnic, national, commercial, souvenir, and advertising purposes, illustrating the multiple paths to which such iconic forms are subjected over time and across cultural boundaries. These paths are not always linear nor are they always debasing in their evolved commercial forms. Bunten (2006) shows how such transformed arts may, in turn, be consumed by the very people who made the originals in the ongoing evolution of their ethnic identity.

By the 1990s, anthropologists were focusing on artistic production, distribution, consumption, and meaning from sources hardly 'outside' (in Maquet's sense) the metropolis itself. In Bright and Bakewell (1995), the contributing anthropologists were literally "Looking High and Low" (the title) in the greater Los Angeles region, covering such cases as Chicano graffiti and murals (Sanchez-Tranqillo 55–88), Low Riders (Bright 89–123), and the aesthetics and politics of representation of Zuni war gods and Hopi *kachinas* (Tedlock 151–172), showing how hegemonic cultural categories of identity produced classifications of products as crafts versus arts and high and low within the latter. In the last chapter, Marcus (173–198) focuses on the John Paul Getty Museum, and dissents from Bourdieu (1984) by asserting that 'high arts' in the United States are supported by the wealthy 'middlebrow' classes, whereas in France, there still was a 'highbrow' elite life style. Continuing the anthropological examination of control of symbolically laden categories, Plattner (1997) has showed how hierarchies of prestige, stemming from New York, control economic rewards that dictate the life choices of a range of professional artists in St. Louis. The inclusion of Western and World arts into the mainstream of anthropology is signaled by Ong's (2012) analysis of a 2008 exhibition at the New York Guggenheim Museum by the Chinese mainstream artist Cai Guo-Qiang.

The anthropology of art overlaps with visual anthropology, which has come to mean a focus on 'modern' forms of representation such as the media, including photography, film, video, television, and computers in themselves or as media through which to analyze more traditional anthropological subjects such as art, ritual, clothing, and performance (Banks and Morphy, 1997; Pink et al., 2004). The study of art also overlaps with the resurgent study of material culture, with a journal of that name founded in 1996. Emphases may be on vernacular or folk materials (Glassie, 1999) but the major thrust of this new Marxist-oriented purview is on ordinary mass-produced objects and their consumption in metropolitan and increasing postcolonial societies (Miller, 1997, 1998) and particularly on personal possessions and the home (Miller, 2010). Miller and his colleagues emphasize how centrally important 'things' are in everyday life, both as expressions of personal and family identity and as items giving meaning to everyday life.

Anthropology as Art as Anthropology

Norwegian anthropologist Arnd Schneider organized a meeting at the Tate Modern Gallery, London, in 2003 to explore the overlaps and possible convergence of *Contemporary Art and Anthropology* (Schneider and Wright, 2006). This volume and many other articles and collections (Schneider and Wright, 2010) examine the methodological and epistemological convergences of contemporary anthropology and art practice. On the one hand, many artists claim that they are doing ethnography, conducting research and revealing the results of their explorations of the world – usually in visual forms – a topic that Taylor (1994) claimed anthropology had long shunned. On the other, since the 'crisis of representation' in the 1980s, many anthropologists claim that their exploration and presentations are as or more convincing for their aesthetic forms than their scientific rigor. Common are works on "the poetics of…," while others focus on creativity in anthropology. While the contributors are about equally divided between anthropologists of many stripes, and artists broadly defined, key authors include anthropologist George Marcus and cultural studies maverick Lucy Lippard who admits to being an archaeologist manquée.

Contemporary Anthropology and Disciplinarity

The anthropology of art and the discipline of art history have long been growing closer and overlapping, especially the 'new art history' (Baxandall, 1972), which emphasized the personal and material relationships and social networks within which art was created; this focus on particular historical societies and cultures rather than formal aspects resembles anthropological emphases on contextualization. The anthropology of art is in

fruitful dialogue with art history in covering the archaeological, non-Western ethnic and cosmopolitan arts of the world. Morphy and Perkins (2006) retrace the history of the subdiscipline, while Venbrux et al. presents papers from the 2003 American Anthropological Association meeting *Exploring World Art* (2006). Svasek (2007) presents a masterful summary of *Art, Anthropology and Cultural Production* (2007) emphasizing the role of emotions. Art historian Leuthold draws upon anthropological works in framing his collection *Cross-Cultural Issues in Art* (2011), whereas in Westermann's interesting collection *Anthropologies of Art* (2005), only Morphy and Errington represent anthropology among the 14 authors who are mainly art historians.

There is a growing field in which the disciplinary boundaries between anthropology, art history, and cultural studies dissolve in synthetic collections in books and in journals such as *Res, Art in America,* or *Visual Anthropology Review,* reflecting the emerging breakdown of the boundaries between art, craft, and material culture and perhaps of the singularity of 'art' itself.

Art History

Horst Bredekamp, Humboldt University, Berlin, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The main task of art history is to collect, preserve, classify, appreciate, and mediate historic artworks of all periods. It deals with materialized forms of historical interventions that shape the concepts of time and thereby continuously change the character of the present. Art history is continuously in conflict with modernism and defines it in the same moment. 'Globalization' can count on a prehistory that goes back before the age of imperialism, but at the same time the traditional concept of art history as 'Image history' (Bildgeschichte) is in danger, caused by the separation between art history and visual studies.

The Character of Time

In the year 1983, the artist Bogomir Ecker had the idea to create an artwork that would not only last for the centuries to come, but would be realized over the inconceivable time span of 500 years; he hence began to search for a place that promised to survive so far into the future. His search was by no means trivial: his artwork, the so-called *Tropfsteinmaschine* (*Dripstone Machine*), required an incessant supply of dripping rainwater for its apparatus to create a sculpture that, through mineral sedimentation, would grow 1 cm every 100 years (Ecker, 1999). Not only the place but also the maintenance of the apparatus had to be warranted for the next 500 years. The first building that came to the artist's mind was the house of parliament in Bonn. However, in 1987, he decided by intuition that even the future of this center of the West German state was too uncertain for it to serve as the site for his installation. History proved him correct, as the Reunification put an end to the 'Bonn Republik'. In his search for a lasting establishment, the artist ultimately decided against a political building and instead chose a museum, the safekeeper of art: With his choice of the Hamburger Kunsthalle, he incorporated his generation-spanning production space into the institution that to him held the highest promise of surviving all future changes, even over the next centuries (**Figure 1**).

This example puts in a nutshell the main tasks of art history, shared with archaeology, namely, to collect, preserve, classify, interpret, and mediate historic artworks of all periods. In doing so, art historians instantiate a concept of time that counteracts the passing of the present. Already the decision to allocate or withdraw means for this expansive task touches a community's identity at the heart. Also oral, textual, and musical tradition provides a space for reflection; but the sphere of visual art confronts the viewers and their projections, which stem from the present, in the unique form of a counterreality that can be scrutinized in its material presence. Therefore, the concept of time developed and maintained by art historians carries a profound social dimension.

Museums at the same time reveal the paradox endeavor of art history. Since the discipline was systematically included in an academic curriculum for the first time in 1810 at the University of Berlin (Bredekamp and Labuda, 2010), art history, through its museums, has left an imprint on modern culture only comparable to the spread of hospitals through the progress of medicine and the erection of temples of transportation, such as train stations and airports, through engineering science. Since the opening of the Altes Museum in Berlin in 1830 (**Figure 2**) – the first autonomous building of modernity constructed for this specific purpose – the permeation of the history of art by art history has exerted an eminent influence on metropolitan life. Through museums, art history contributes to the urbanity even of small- and medium-sized towns, but also of metropoles such as Berlin, London, Madrid, Paris, Mexico, New York, and Beijing. Whenever newly developed centers wish to document their supraregional relevance, these claims find expression in the erection of museums: recent examples are Abu Dhabi (**Figure 3**) and Hong Kong. As a hard factor contributing to the attractiveness of human communities, museums in their paradoxical construction have remained unchallenged over almost 200 years; and even

Figure 1 Bogomir Ecker, Dripstone Machine, Installation, 1996, Kunsthalle, Hamburg.

Figure 2 Friedrich Alexander Thiele, View of Karl Friedrich Schinkel's museum of Berlin, colored etching, 1830.

Figure 3 Frank Gehry, Model of the museums in Abu Dhabi, 2007.

presently, the continuing increase of visitor streams conveys no trace of fading appeal. The 100 most visited art museum range between the Palace Museum in Beijing (*c.* 12 million visitors per annum) and the Istanbul Modern (*c.* 666 000 visitors). The 100 most frequented exhibitions of the year 2012 range between *c.* 10 500 (Tokyo, Metropolitan Art Museum) and *c.* 160 000 (Stockholm, Moderna Museet) per day (Source: Visitor Figures, 2012). The numbers for Europe can be checked regularly through the *European Group on Museum Statistics* (www.egmus.eu/en/statistics/).

As a warrantor of the diachronic development of art, however, art history stands in conflict with a modernity that it brought forth itself. Modernity calls for acceleration, presentism, and creative destruction, which in the Futurist Manifesto of 1909 comprised the destruction of all museums as a prerequisite for further development. The fact that art history, by having integrated Futurism into the historical conditions of the Modern Canon, bears this conflict within itself, is evidence for the paradoxical disposition of the discipline in the modern world.

Space: Globalization

This conflict affects all aspects of art history's presence in our days. Because art history has a century-old history, it has to reinvent itself by providing new answers in conflicting fields, of which the problems of globalization are perhaps the most pressing.

The criteria for form analysis, comparison, and the history of form development and the search for iconological semantics, which has been differentiated into a variety of within themselves highly complex stylistic periods, have been developed and refined since the age of the so-called 'father of art history', Giorgio Vasari, mostly with regard to European art; however, over the centuries, the criteria have been tested and improved in most diverse ways.

From this, two possibilities arise for the future. According to the first, these methods hold a similarly objective status as Euclid's geometrical laws, able not only to transcend time but also to operate transculturally. This precludes their continuous discussion and repeated adaptation to new subject matters. According to the second possibility, these methods must be defined as historically determined skills that will be transformed in an undetermined future within a new framework, in which they will unfold their meaning in a different way. The future beneficiary of such a process would then have to compensate possible losses of the historical methods.

This fundamental question is related to the European origin of the discipline. The Western industrial countries have brought forth by far the most art historians. However, from the beginning, it was considered a sign of quality not to confine art-historical studies to the art of one's own culture but instead to explore the congruent as well as antagonistic intertwinings between different cultures. Regarding the artifacts of the so-called 'Third World', the colonial aspect of this phenomenon is not far to seek; but the interest in foreign cultures was, albeit less frequently, also motivated by curiosity and high regard for other domains. For this reason, those museums that stem from the tradition of the *Kunstkammer* had to deal with the internal conflict that their collections were predominantly the products of colonial overthrows, but also of a non- or anticolonial interest and admiration (example of a scholar, Nicolas-Claude Fabri de Peiresc: Miller, 2012; feathers as an example of shaped materials: Russo, 2002; Penacho, 2012; in general: Götterbilder, 2012). In this lies the second open question that the discipline is confronted with today.

An early, liberal answer to the problem is Franz Kugler's magnum opus of liberal globality, the *Handbuch der Kunstgeschichte* (*Handbook of Art History*), published in 1842 (Kugler, 1842; Franz Theodor Kugler, 2010). Written in the climate of Johann Gottfried Herder's definition of the *Weltbürger* (world citizen), the text tries to unite all artworks from the Stone Age to the present in a non-hierarchical narrative. Through the deepening of nationalisms in the second half of the nineteenth and above all in the twentieth century, this global orientation was lost for the most part. A fortiori, the non-colonial interest in foreign art today has become a driving impulse in most of the contemporary debates worldwide (Crossing Cultures, 2009).

It was a programmatic decision of the founders to locate the *Getty Center* as one of the most ambitious research institutes for art history and material culture worldwide, not on the East coast of the United States, but instead in Los Angeles, to make strong its pacific perspective (**Figure 4**). The process of transcending borders regarding materials and cultures is spurred by the umbrella organization *Comité International d'Histoire de l'Art* (CIHA). The CIHA was founded after the Second World War to counteract the mental and material destructions of fascism and National Socialism. Until recently, all world congresses, which are organized by the CIHA every 4 years since the first Vienna congress in 1973, had taken place in Europe and the United States. In 2008, the first congress to take place in the Pacific Rim was held in Melbourne, as a statement regarding the spread of art history throughout the world. While 50 nations convened there at the time, the CIHA-congress in Nuremberg 2012 brought together art historians from unprecedented 82 nations. The congress of the year 2016 will take place in Beijing. Further, no less telling symbols of this global orientation are two encyclopedias: the *Dictionary of Art* (1996) and the German-language *Allgemeines Künstlerlexikon* (General Artist Lexicon, 1991ss.), dedicated to the artists of all times and peoples (the online-edition already contains over 1 million entries (http://www.degruyter.com/view/db/akl)).

In view of this comprehensive documentation of artists and artworks of all times, the methodological globalization of art history lies not merely in adding new fields or ordering existing ones but in developing perspectives that emphasize tensions and differences and thereby produce criteria for assessing the respective strengths and weaknesses. The study of perspective in different cultures can function as an example for this (Is Art History Global? 2007; Kritische Berichte, 2012) as well as the reformulation of crossing cultures in larger areas like the Mediterranean (Wolf, 2009).

An attempt was made to increase this problem awareness also institutionally by internationalizing the directorship of major art-historical institutions. Hence, in the year 2013, an Australian art historian is the director of the Norwegian museum in Trondheim, while a Norwegian art historian directs the National Museum in Mombasa; a German ethnologist and art historian is the head of the Victoria and Albert Museum, while – the perhaps most historic example – a curator educated in Herder's sense, who was born in Nigeria, worked in Africa and the USA, and curated the documenta 11 in Kassel in 2002, since 2011 heads the *Haus der Kunst* in Munich – a museum that was inaugurated by Adolf Hitler in 1936. This tendency was pushed to an almost Dadaistic extreme at the Venice Biennial in 2013, where France and Germany exchanged their pavilions and Germany featured foreign artists, among them the Chinese Ai Weiwei (La Biennale di Venezia, 2013). Taking all of these answers to the question of

Figure 4 Richard Meyer, Getty Center, Los Angeles, 1991–1997.

globalization, it appears that the universal self-definition of the discipline has been sealed also for the future.

Image: Art History as Bildgeschichte (Image History)

One of the conditions of this process is the reactivation of a wide definition of 'art' as developed mainly in the German-speaking realm of Austria, Switzerland, Germany, and several eastern European countries throughout the nineteenth and twentieth century until the fatal year of 1933. 'Art' was not understood as an autonomous, self-obliging form of creativity, but in the sense of the Greek *techné* and the Roman *ars*. This meant that not only the products of high art but also all forms of applied arts lay in the responsibility of art historians. The museums of art and design have lived up to this standard worldwide.

Important representatives of this direction were Franz Kugler, Gottfried Semper, Alois Riegl, and Aby Warburg. Namely Riegl (1985) and Warburg (Warburg, 1998, 1999) set a still relevant example for the ability of art historians to overcome the inner paradox of the discipline, i.e., to stand in the present and simultaneously secure the timeless quality of the artworks, to be devoted to every kind of form (*Gestaltung*) by emphasizing the unique character of the visual arts while also realizing the finesse of the applied arts.

Within this framework, art historians appropriated new media such as photography and film not only as parts of a new corpus of visuality but also as methodological enrichments. The early theory of film by Rudolf Arnheim (1931) became a landmark in film studies that were founded through the continuous activity of Erwin Panofsky (Bredekamp, 2006). What is more, all forms of video (the earliest attempt was: Film als Film, 1977) and digital media – such as web art – were quickly analyzed and adopted. The medias of video and digital art are included in many museums, and the *Zentrum für Kunst und Medientechnologie* in Karlsruhe (1996) has for the first time devoted an entire complex to these new media, consisting of both an art museum and a laboratory. As the response to a media revolution encompassing the world but remaining ephemeral in its production, museums as the primary seats of art history remain the fixed points of a locally accessible but materially permanent realm of experience, one that also incorporates the products of the art-technological revolution.

Against common intuition, art history was one of the first humanities to support the use of computers as an auxiliary means for archiving and searching (Kohle, 2013). One of the oldest and most successful digital programs within the humanities may be the *Census of Antique Works of Art and Architecture Known to the Renaissance*, whose presentation in Pisa in 1983 and in London in 1992 set the course for the discipline as a whole (Nesselrath, 1993). The search engines of the image archive *Foto Marburg* (www.fotomarburg.de), the *Prometheus Image Archive* (www.prometheus-bildarchiv.de), *Digitale Diathek* (www.digitale-diathek.net), and the Andrew F. Mellon Foundation's ARTstor (www.artstor.org) have achieved in the field of images what the Getty Research Portal of the Getty Research Institute has developed for digital research in art-historical literature (www.getty.edu/research/tools/portal/index.html) and what other institutions have created for the documentation of national art (e.g., in the Netherlands: www.rkd.nl) or national collections (e.g., France: http://www.culture.gouv.fr/documentation/joconde/fr/pres.htm). Nearly every larger museum has in recent years made at least parts of its collection accessible online as digital reproductions, and the Department of Prints and Drawings of the British Museum set an example regarding the free use of images in the sense of open access (www.britishmuseum.org/research/collection_online/search).

Furthermore, the products of everyday culture have been and continue to be a systematic subject of this type of art history. Already at the beginning of the twentieth century, Warburg suggested the use of the term *Bildwissenschaft* (image science) to better describe the subject matter of the discipline.

After National Socialism severed this tradition, it has been successfully reestablished since the 1960s (landmarks: Freedberg, 1989; Belting, 2001; Didi-Huberman, 2002). If today the image worlds of the natural sciences and medicine (Das Technische Bild, 2008; The Technical Image, 2013) and most notably political iconography (Handbuch der Politischen Ikonographie, 2011) belong to the natural areas of art-historical analysis, then this is an effect of the renaissance of a once dominant tradition.

A part of this revival is also the close relationship between art history, philosophy, and linguistics as it was developed at the cultural historical library *Kulturwissenschaftliche Bibliothek Warburg*, the work of whose members gave some of the most important impulses that ever came from art history. Attempts have been made to resuscitate this tradition as well, which was mostly destroyed after the library's emigration to London in 1933. If the present period has been placed under the terms *pictorial turn* (Mitchell, 1992) and *iconic turn* (Boehm, 1994), this by no means implies playing off images against language. Instead, what is at stake is to radically question the interpretive predominance of language championed by the *linguistic turn*. Both *turns* are related to the conviction that in a highly technologically advanced civilization in which communication takes place for the most part visually it becomes all the more necessary to develop a philosophy of the image that is equal to the present task.

The collaborative effort between *Embodiment Theory* (Krois, 2011) and *Picture Act Theory* (Theorie des Bildakts, Bredekamp, 2010) has tried to answer these demands. Also in this endeavor, artifacts have been examined in their entire breadth, from automatons to diagrams.

Material, Language, Visual Studies

However, at the same time, these achievements are threatened by the breaking away of visual studies from art history in the English-speaking realm (Elkins, 2003; Bredekamp, 2003; Art History and Visual Studies in Europe, 2012). This has had the effect that Anglo-Saxon art historians tend to feel relieved of the pressure to face the entire breadth of the discipline as it was conceived by Riegl and Warburg. This contradicts their own tradition that tried to embrace the whole frame, as developed from most different perspectives by scholars like George Kubler (1962), David Freedberg (1989), Barbara Stafford (1991), James Elkins (1999), Whitney Davis (2011), and Neil MacGregor (2011). Although representatives of visual studies have succeeded in opening up everyday visual culture to scholarly research in a remarkable way, they also have to account for dire losses. By distancing themselves from art-historical methods, the sensitivity for the value of each individual form becomes less developed.

This process creates the third profound problem, strengthened by developments in language policy. While up to the year 1933 the dominant language of art history was German, the CIHA committee chose English, French, Italian, and German as the official congress languages. In 2004 Spanish was added. So far, each language, independent of nationality, has brought forth specific modes of thought that defy immediate translation. Conjointly, the five internationally defined languages, to which, depending on context, must be added Arabic, Chinese, Japanese, Netherlandish, Russian, Portuguese, and all other languages in which the respective artworks have been reflected, have generated methodological diversity and a fruitful wealth of perspectives. The globalization of science in general, however, has also caused art history to increasingly sacrifice its plurality of languages to the predominant use of English. Despite all the advantages of facilitated mutual understanding, a danger is involved that threatens art history at its core; in this lies the major problem and potential of art history today.

With the global transition toward English as the universal language of art history, the danger of a methodological reduction of the discipline lights up and could cause its marginalization. Art history will continue to be responsible for the high arts inalienably and for indeterminable time to come. With regard to the deeper-lying battlefields of coming to terms with a visually dominated contemporary culture, however, art history could be pushed into a minor role, or even worse, cease to play any role at all. Its future disciplinary as well as social reputation depends on the solution of this conflict.

Artificial and Natural Computation

Achim G Hoffmann, The University of New South Wales, Sydney, NSW, Australia

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article discusses the notion of computation in natural as well as in artificial systems. Particular emphasis lies on artificial computation models that are derived from natural systems that perform computation. The article sketches the main direction of research in the past decades on modeling computational processes in natural systems. This concerns on the one hand computation in nervous systems, such as the human brain and their artificial models. On the other hand there is the process of biological evolution, of which artificial computer models proved very useful as a general approach to solving difficult design and optimization problems.

In the 1930s, a precise mathematical notion of computation had been developed, which captures everything that can be computed in our modern computers. What exactly natural computation is and how it is conducted in natural systems, such as the human brain, is less well understood. However, the mathematical notion of computation proved a convenient and very useful form for describing information processing in natural systems.

Wiener (1948) introduced the discipline of cybernetics, which was concerned with control systems, including natural systems, such as the human body, in which feedback loops control the secretion of glands.

In the following decades, computational models of biological systems were developed and used to address a variety of difficult problems for which conventional solutions were not readily available. The research on models of natural computation has focused mainly on models of the human brain and its neurons on the one hand and on biological evolutionary processes on the other hand.

Another type of computation in 'natural systems' was shown by Adleman (1994), when he demonstrated the use of DNA molecules as a means of solving computational problems. The work showed the potential for building computers on the basis of molecular biology.

This article focuses on the main research efforts in the past decades and discusses artificial models of natural computation in neural systems. Furthermore, the use of models of biological evolution for solving computational problems will be sketched.

The article is organized as follows: first, the mathematical notion of computation is discussed. This is followed by a description of computation in those natural systems, for which most of the artificial models of natural computation have been developed: the human brain and evolutionary processes in biology. The relationship between the natural computing processes and the artificial models are discussed thereafter.

The Mathematical Notion of Computation

In the 1930s, it was an important problem in mathematics to delineate those function definitions for which the function value can be computed for all possible arguments from those functions for which the function value may not be effectively computable. (For functions that contain themselves either directly or indirectly in their definition, it is not straightforward to decide whether a value can effectively be determined for all possible arguments.)

Turing (1937) developed a model for what a mathematician can possibly do, when computing the value of a function according to clearly defined rules, and he argued that no human mathematician could possibly follow other clearly defined rules that are not covered by his model. This model became known as the Turing machine. Other mathematicians developed alternative models for how to effectively compute mathematical functions. However, it was proved that with all these different models, exactly the same class of functions was effectively computable.

The Turing Machine

A Turing machine has a finite number of internal states. A tape on which the Turing machine can read and write symbols from a finite alphabet via its read/write head is unlimited on both sides. The Turing machine starts its operation in a particular internal state and terminates its operation in another particular state. The read/write head will focus on the first square on the tape, where the input string (in consecutive squares) for computation is provided. The Turing machine will execute a sequence of operations. Each of these operations depends on the current symbol under the read/write head and its internal state. The operation may erase the old symbol on the tape in the square under the read/write head and replace it by another symbol. Furthermore, the Turing machine may change its internal state and move (optionally) its read/write head one square to the left or to the right. The entire computation terminates when the Turing machine reaches the special internal termination state. The result of the computation is found at a prespecified location on the tape relative to the position of the read/write head. Which operation is executed depends on the internal state and the current symbol under the read/write head and is specified in the corresponding Turing table. An example is shown in Figure 1.

An important concept is the universal Turing machine, which is a special Turing machine that is capable of simulating any other Turing machine, if a description of that machine is provided as input on the tape. The existence of the universal Turing machine demonstrates the relativity of the actual device on which the computation is performed. Generally speaking,

State	Symbol		State	Symbol	Head
1	A	→	3	B	R
1	B	→	2	C	L
1	C	→	6	C	L
...	...		...	...	...
...	...		...	...	...
6	D	→	3	A	R

Figure 1 The schema of a Turing machine (left) and the corresponding Turing table defining the operations of the Turing machine (right).

a computing device can behave in quite different ways depending on what data are provided to it. In the case of a computationally universal computing device, all other computing devices can be simulated, if appropriate data, i.e., an appropriate program, is provided.

Today's computers are generally said to be computationally universal. Hence, natural computation can, in principle, always be simulated on an artificial computation device. In practice, however, enough is not known about what 'programs' are actually 'executed' in natural computation processes.

Artificial and Natural Computation in Neural Systems

Artificial computation in artificial neural networks is a metaphorical model of natural computation in biological neural systems, such as the human brain.

Usually, large sets of computing units, connected in a network-like manner, are used to simulate the way natural neural networks in man and animal perform information processing. Often, the involved computing units are all of the same type and compute some sort of linear threshold function, i.e., they sum up the weighted input signals and compare the sum against a threshold value. This simple model of a neuron's functionality is due to McCulloch and Pitts (1943).

The unit computes internally the function

$$f(i_1, \ldots, i_n) = \sum_{j=1}^{n} w_j i_j$$

where i_j is the jth input and w_j is the weight associated to the jth input. This internal function is used to calculate the output value by applying, e.g., a sigmoid function to it, such as

$$\text{out} = \frac{1}{1 + e^{-af(i_1,\ldots,i_n)}}$$

with a scaling parameter a. This maps the internal function value in the range of $[-\infty, \infty]$ to a value in the range [0,1] strictly monotonically as shown in Figure 2 (right). The weights for each individual unit usually vary and are often determined by an automatic adjustment process, also called training or learning. The first well-known learning algorithm for such neuronal models had been developed by Rosenblatt (1962), who used a step function as opposed to the mentioned sigmoid output function.

Artificial neural networks are usually composed of a large number of these units; e.g., in engineering applications, the number of units typically ranges between ten and several thousands. The units are normally arranged in a layered fashion, similar to the structure in Figure 2 (left), where the outputs of the units on one layer are fed as inputs to the units on the next layer. Such networks are also known as multilayer perceptrons (usually abbreviated as MLP since the hallmark publication of Rumelhart et al. (1986)). See also Figure 2 (left). In combination with learning techniques that find appropriate weights for each unit, these networks have been successfully applied to a large number of engineering problems; for general classification problems; for recognition of visual, acoustic, and other patterns; for adaptive control of nonlinear systems; and many other types of problems.

It must be noted that the computational models of cognitive systems are not at all accurate replications of what is known about their biological functionality. To contrast the artificial neural networks, the following presents some of the current knowledge about the physiological basis of computation in the human brain.

Natural Computation in the Human Brain

The human brain is made up of a vast network of neurons coupled with receptors and effectors. The input to the network is provided by millions of receptors while the output from the brain is transformed into effects on our body and the external world via effectors. The receptors continually monitor changes in the internal and external environment. Hundreds of thousands of cells control the effectors, such as muscles and the secretion of glands.

The human brain is made up of thousands of millions of neurons. A typical estimate is about 10^{10}–10^{11}, i.e., 10–100×10^9 neurons. Many neurons have between 1000 and 10,000 connections to other neurons in the brain. There are thousands of different types of neurons in the brain. This includes neurons whose purpose has been identified as being specialized to the processing of sensory information. Those specialized neurons that deal directly with the signals coming from sensors, which are receptors for light, sound, touch, etc., are called sensor neurons. Other neurons are responsible to control our muscles and are, therefore, called motor neurons.

Figure 2 Left: A feed-forward neural network (multilayer perceptron). Right: A sigmoid output function.

The brain can hardly be considered as a simple stimulus–response chain from receptors to effectors. The vast network of billions and billions of neurons is rather interconnected in extremely complex and diverse ways, including simple loops as well as complex feedback cycles. Thus, signals coming from the receptors are mixed with signals already traveling in this vast network resulting in a change of the signals traveling inside the network as well as to generate signals for controlling the effectors.

In that way, the brain, or the central nervous system, manages to generate actions that depend on both the current stimulation as well as on some residue of past experiences. Past experiences may be reflected in current activities of the network, i.e., certain signals traveling inside the network as well as the current pattern of connections.

There are more than 1000 different types of neurons estimated to occur in the human brain. As a consequence of the large variety of neurons in the brain, it is impossible to speak of the typical neuron. However, a model of a neuron is sketched in Figure 3, which captures some of the basic features and functionality found in many different types of neurons.

More than 40 properties of biological neurons are known to influence a neuron's information processing. One distinguishes three different parts in biological neurons: soma, axons, and dendrites (Figure 3). Biological neurons are connected with each other. Their connections are called synapses. The axon may be considered as the output channel of the neuron, which conveys its activation level to the synaptic connections with other neurons. The ends of the axons are called nerve terminals or endbulbs. The dendrites on the other hand act as the neuron's input receptors for signals coming from other neurons. They convey the (electrical) input potential to the neuron's soma, i.e., to the neuron's body. The input potential in that case is also called postsynaptic potential. The neuron's soma, in particular where it connects to the axon, i.e., in the axon hillock, acts as an accumulator of input potentials and/or as an amplifier of these signals.

Figure 3 A schematic view of a neuron. The activity coming from receptors or from other neurons changes the membrane potentials on the dendrites and cell body (soma). The effects of these stimulations accumulate at the axon hillock where, for appropriate spatiotemporal patterns of stimulation, a threshold is reached, which triggers a pulse of membrane potential to be propagated along the axon. This pulse is carried via the branching of the axon to the synaptic endbulbs, which in turn stimulate the membrane potential of the neurons or muscle fibers to which the synaptic endbulbs are connected. The dashed arrows indicate the direction of activity propagation through the axons.

The tips of the branches of the axon impinge upon other neurons or upon other effectors. The locus of interaction between an endbulb and the cell upon which it impinges is called a synapse, and one says that the cell with the endbulb synapses upon the cell with which the connection is made. In fact, the axonal branches of some neurons can have many 'endbulbs' that allow them to make synapses along their lengths as well as their ends.

Dynamics of Biological Neurons

Neural activations are mostly circularly stimulated. A neuron is activated by other neurons to which it is connected. In turn, its own activation stimulates other connected neurons to activation.

If an impulse is started at any one place on the axon, it propagates in both directions. However, if the pulse is started at one end of the axon (normally the axon hillock), it can travel only away from that end, since once a section has been triggered it becomes refractory until well after the impulse has passed out of range. An impulse traveling along the axon triggers new impulses in each of its branches, which in turn trigger impulses in their even finer branches. Axons come in two kinds: myelinated and unmyelinated. A myelinated fiber is wrapped in a sheath of myelin, a sequence of Schwann cells wrapped tightly around an axon with small gaps, called nodes of Ranvier, between adjacent segments. Instead of the somewhat slow active propagation down an unmyelinated fiber, the nerve impulse in a myelinated fiber jumps from node to node, thus speeding passage and reducing energy requirements. When an impulse arrives at one of the endbulbs, after a slight delay it yields a change in potential difference across the membrane of the cell upon which it impinges. The membrane on the endbulb is called the presynaptic membrane, and the membrane of the surface upon which the endbulb impinges is called the postsynaptic membrane. At most synapses the direct cause of the change in (electrical) potential of the postsynaptic membrane is not electrical but chemical. There are some exceptional cell appositions that are so large or have so tight coupling that the impulse affects the polarization of the postsynaptic membrane without chemical mediation. However, the normal process is that the electrical pulse that reaches the endbulb causes the release of transmitter molecules from little packets called vesicles through the presynaptic membrane. The transmitter then diffuses across the very small synaptic cleft to the other side. When the transmitter reaches the postsynaptic membrane, it causes a change in the polarization of this membrane. The effect of the transmitter may be of two basic kinds: either excitatory, tending to move the potential difference across the postsynaptic membrane in the direction of the threshold (depolarizing the membrane), or inhibitory, tending to move the polarization away from the threshold (hyperpolarizing the membrane).

The many small changes in potential differences across the membrane of a neuron, due to the activity of many or all the synapses that impinge upon it, propagate – in most

cases – passively through the membrane of its dendrites and its cell body. They decay as they propagate. At the axon hillock, many different and often small potential changes converge, so that the total contribution by which excitation exceeds inhibition may be quite large. In other words, the transmitter released when the impulse of a single synapse arrives at the endbulb, and generally causes a change in the postsynaptic membrane, is usually not large enough to trigger the neuron. Nonetheless, the cooperative effect of many such subthreshold changes may yield a potential change at the axon hillock that exceeds threshold, and if this occurs at a time when the axon has passed the refractory period of its previous firing, then a new impulse will be fired down the axon. See Arbib (2003) and Bower (1997), or the *Journals Biological Cybernetics*, *Journal of Neurobiology*, and others.

From the description it is clear that the current artificial neural networks are only very rough approximations of the natural neural systems. Furthermore, it has been proved that certain types of artificial neural networks (cellular automata) are even computationally universal. This, however, implies also that nothing has been gained from the natural role model with respect to the function the cellular automata will compute. The function depends completely on the 'activity levels of the individual cells.' That is, with suitable initial activity patterns the system can compute any function one chooses.

Evolutionary Computation

Evolutionary computation is another field, which is strongly inspired by nature. This field was pioneered independently in the 1960s by Rechenberg (1973) and Holland (1975); both published their work in books only in the 1970s. Rechenberg used evolutionary strategies to develop highly optimized devices, such as irregularly shaped reduction pieces for pipes, e.g., for air conditioning, which proved to have lower air flow resistance than ordinary reduction pieces.

In evolutionary computation, the process of natural evolution is used as a role model for a strategy for finding optimal or near-optimal solutions for a given problem. In genetic algorithms, an important class of evolutionary computing techniques, candidates for a solution are encoded in a string, often a binary string containing 0s and 1s only. Evolution takes place by modifying the genetic code of a candidate.

Evolutionary techniques are generally applied to optimization problems. Many of those problems are combinatorial optimization problems, which are computationally hard (NP-hard). This means roughly that programs are expected to require a computing time that grows exponentially with the size of the problem. One such problem is the traveling salesperson problem, where a number of cities are given along with a distance matrix providing the traveling distance or cost for each pair of cities. The problem asks for the shortest possible round trip, i.e., the traveling salesperson departs from a given city and should visit all other cities before returning to the first city. For n cities, apart from the city of origin, there are $n!$ different round trips. A substantial proportion of them has to be evaluated before one can be sure that the optimal round trip has been found. Hence, the number of computing steps grows exponentially with the number of cities to be visited. That is, the required computing time to find the optimal solution becomes impractical even for moderate numbers of cities on today's fast computers and those computers of the near future. As a consequence, one has to be content with a good solution as opposed to an optimal solution.

The traveling salesperson problem can be handled by a genetic algorithm according to the following sketch: a population of potential solutions (more or less randomly generated orderings of the cities) is created initially as the first generation in the evolutionary process. The fitness of each individual for a solution to the posed problem is assessed, i.e., the traveling distance is calculated. The better suited individuals in the population, i.e., those with smaller traveling distances, will be retained and the less fit individuals are discarded when the next generation is created. In addition to the retained individuals are new individuals created as 'offsprings' from the current population. Offspring individuals are usually created by random mutations of the 'parents.' This may also include the combination of the genetic code of multiple parents, such as 'crossover' operators on the genetic code of two parent individuals.

From a more abstract point of view, such evolutionary approaches fall into the category of probabilistic algorithms. Other probabilistic algorithms, such as simulated annealing (which constitute another computer model of a natural, physical process), share the following common feature with the sketched genetic algorithms: a solution to the given optimization problem is developed by iteratively modifying one or more candidate solutions until a satisfactory solution is found. The iterative modification is based on some random decisions. Usually, a fitness measure is used to decide whether a new candidate solution is deemed any closer to an acceptable solution than previously generated candidates. Consequently, if a new candidate appears closer to an acceptable solution, the new candidate will normally be used to derive another modification. This is also called hill climbing in a search space. However, since no exact measure for the closeness of a candidate to an acceptable solution can generally be expected, a candidate that appears less close to an acceptable solution may still be selected for modification, but with less probability.

While the evolutionary strategies appear to be universally applicable, experience showed that in most cases problem-specific adaptations of the evolutionary scheme need to be made in order to allow the evolutionary process to generate a good solution in reasonable computing time. Such adaptations may consist of finding a suitable genetic encoding of a solution candidate and determining an effective size of the population, suitable probabilities for generating mutations, etc. Another application of the sketched genetic techniques is the development of programs, as it is done in the field of genetic programming. See Koza et al. (1999) for more details. For more details on evolutionary computation, see, e.g., Rozenberg et al. (2012).

Other Approaches

Various other ideas have been put forward about how processes from nature can be used to build computational systems. These include the following:

- Swarm intelligence: these systems utilize observations from animal swarms such as ants, fish, or even bacteria, where

a collective information gathering process can be seen that is utilized in order to optimize the behavior of the group. For example, ants have been found to use pheromones on their way back to the nest, when they have found a food source. As a consequence, other ants can perceive the relevant information about where they can find food. If multiple food locations were found by multiple 'explorer' ants, the strengths of the pheromone trails would indicate in what region perhaps even more food sources may be found. See, e.g., Engelbrecht (2006) for further reading.

- Membrane systems: these systems are based on the idea of using compartments that are separated by membranes. Inside the compartments a number of objects can reside and can be manipulated in parallel according to specific rules for each compartment (corresponding to a biological cell). Certain rules apply when an object can migrate from one compartment to another (i.e., moving through a membrane). Such a system can again be applied to optimization problems or be used to simulate the actual processes occurring in biological cells. See, e.g., Cardelli (2005).

Summary and Prospects

The presented artificial computing models of natural processes were the most studied models in recent years. They were models of biological neural systems and models of evolutionary processes in biology.

While nature inspired substantial research on these models, the models are rather metaphorical models of the natural processes. Many known details of the natural processes are missing in these models. The models are not accurate, and they are not meant to be accurate. Once simple models were developed, they were studied for their use in particular applications, such as solving certain combinatorial optimization problems or learning to classify images of characters. Hence, from an engineering perspective it is less important whether the models represent the natural processes authentically, as long as the models are useful for solving practical problems.

In regard to artificial neural networks, it is certainly desirable to enhance their capabilities, so that they come closer to the performance of the human brain. Given the substantial gap between the artificial models and what is known about the brain's physiology, an accurate computational model of the brain's physiology is not in sight. While it is unknown to what extent the brain's physiology need to be modeled in order to produce a behavior, which would be comparable to a human, it seems likely that not all aspects of the physiology need to be modeled. Which aspects are necessary and sufficient is unknown at this stage.

The artificial evolutionary computation models are no accurate models of the biological processes either. However, their application in engineering and elsewhere are clearly directed toward artificial domains, i.e., engineering problems. Hence, one would not expect that the evolutionary computation models need to be accurate models of biological evolution.

It remains an open question, however, how far will the study of such metaphorical models of nature lead? Perhaps, there exist more suitable approaches that have no resemblance with nature. After all, there are plenty of examples, where excellent engineering solutions are very different from what is found in nature, for example, the invention of the wheel or the steam engine. On the other hand, there are also examples where a partial, metaphorical model of nature's solution to a problem can be supplemented with an artificial engineering approach, for example, the development of airplanes, which do not move their wings, but have rather 'artificial' propulsion mechanisms. See also Hoffmann (1998) for a discussion of the requirements of a computing model for being used as an engineering approach to the design of complex systems.

Artificial Intelligence: Combinatorial Search

Richard E Korf, University of California, Los Angeles, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Combinatorial search is the study of computer algorithms designed to solve problems by systematic trial-and-error exploration of possible solutions. Problem-solving tasks include single-agent path-finding problems, such as the Fifteen Puzzle, two-player games, such as chess, and constraint-satisfaction problems, such as the Eight-Queens problem.

Single-Agent Path-Finding Problems

A classic example of a single-agent path-finding algorithm is the *Fifteen Puzzle* (Figure 1). It consists of a 4×4 frame containing 15 numbered tiles and an empty or blank position. Any tile horizontally or vertically adjacent to the blank can be slid into the blank position. The *states* of the problem are the different permutations of the tiles, and the *operators* are the legal moves. The task is to rearrange the tiles, via a sequence of legal moves, from some random initial state into a particular goal state, such as that shown in the figure, ideally using the fewest moves possible.

A search algorithm may be systematic or nonsystematic. A *systematic search algorithm* is guaranteed to find a solution if one exists and may also guarantee a lowest-cost or optimal solution. If no solution exists, a systematic algorithm may or may not detect this fact. Nonsystematic algorithms, such as *simulated annealing*, *genetic algorithms*, *tabu search*, and other *stochastic local search* algorithms, are not guaranteed to find a solution even if one exists and are not considered here.

The simplest systematic search algorithms are *brute-force search* algorithms, which do not use any knowledge about the problem other than the states, operators, initial state, and a description of the goal state. For example, *breadth-first search* starts with the initial state, generates all states that can be reached from the initial state with one operator, then all states two operators away, etc., until a goal state is reached. *Uniform-cost search*, or *Dijkstra's* single-source shortest-path algorithm (Dijkstra, 1959), allows operators to have different costs and visits states in increasing order of their total cost from the start, where the cost of a state is the sum of the operator costs on the path from the initial state to the given state. A drawback of both these algorithms is that they require enough memory to store all the states generated, which is prohibitive in large problems.

4	5	6	7
8	9	10	11
12	13	14	15

Figure 1 Fifteen Puzzle.

Alternatively, *depth-first search* applies a sequence of operators from the initial state until some depth limit is reached. It then backtracks to the last state that has not been completely explored and applies a new sequence of operators from there. The primary advantage of depth-first search is that it only requires enough memory to store the current operator sequence from the initial state.

A drawback of all brute-force search algorithms is that they do not consider the location of the goal until it is reached. In contrast, a *heuristic search*, such as the *A* algorithm* (Hart et al., 1968), makes use of a *heuristic evaluation function*, which estimates the cost to reach a goal from any given state. For example, *Manhattan distance* is a common heuristic estimate for the Fifteen Puzzle. It is computed by counting the number of grid units each individual tile is away from its goal position and summing these values over all tiles. For every state n visited by A*, it adds the number of moves made from the initial state to reach state n, $g(n)$, to the heuristic estimate of the number of remaining moves to a goal, $h(n)$, to estimate the total number of moves on a path from the initial state to a goal that passes through state n. A* starts with the initial state and generates all the states one move away from it. It then evaluates those states using the cost function $f(n) = g(n) + h(n)$. At each step, it generates and evaluates the neighbors of an unexplored state n with the lowest total cost estimate, $f(n)$. It stops when it chooses a goal state to expand next.

A* is guaranteed to find a solution if one exists. Furthermore, if the heuristic function $h(n)$ never overestimates actual cost, A* is guaranteed to find a shortest solution. In the Fifteen Puzzle, for example, since each tile must move at least the Manhattan distance to its goal position, and each move only moves one tile one grid unit, Manhattan distance is a lower bound on the actual number of moves required to solve any given state. Thus, A* using the Manhattan distance heuristic function is guaranteed to find a shortest solution to the Fifteen Puzzle, if one exists, given sufficient memory.

The drawback of all combinatorial search algorithms is *combinatorial explosion*. For example, the Fifteen Puzzle contains $16!/2 \approx 10^{13}$ different reachable states. Even at a 100 million states per second, a brute-force search examining all these possibilities would take over 29 hours. The 5×5 *Twenty-Four Puzzle* contains $25!/2 \approx 10^{25}$ states. At a 100 million states per second, brute-force search would take over 2.4×10^9 years. With heuristic search techniques, optimal solutions have been found for both the Fifteen and Twenty-Four Puzzles, but not for the larger versions.

Figure 2 Minimax search tree example.

Two-Player Games

The classic *two-player game* is *chess* and has been an object of research in artificial intelligence for over 60 years. In 1997, an IBM machine named Deep Blue defeated Garry Kasparov, the world champion at the time, in a six-game match. The current best programs are comparable to the best human players. The standard algorithm for these problems is *minimax search* with static evaluation, described below, and *alpha–beta pruning*, a technique that makes minimax search much more efficient. The states of the problem are the legal board positions, and the operators are the legal moves of the game. From the current board position, minimax search considers all the legal moves, then all the possible responses by the opponent, then all the possible countermoves to those, etc. In small games, like *tic-tac-toe*, there is sufficient time for the machine to explore the entire *game tree*, or all possible plays by both players, allowing the machine to play perfectly.

In more complex games, brute-force search and hence perfect play are impossible. For example, the chess game graph is estimated to contain over 10^{40} different board positions. In that case, the machine searches ahead as many moves as it can, given the time available to make each move. The limit of how far it can look ahead is called the *search horizon*. Each of the game states at the search horizon is then evaluated by a heuristic function that returns a number, which estimates the relative merit of that board position for each player. A large positive value is advantageous for one player called MAX, and a negative value of large magnitude is beneficial to the player called MIN. For example, the simplest evaluation function for chess would sum all the pieces on the board belonging to MAX, weighted by their relative values, and subtract the weighted sum of all of MIN's pieces on the board, to get the relative material advantage of MAX over MIN. A weighting function for chess might count the queen as worth nine points, the rooks as five points each, the bishops and knights as three points, and one point for each pawn, for example.

Given the numeric evaluation of the board positions at the search horizon, the move to make is computed by the minimax algorithm. The value of each position in the game tree is computed recursively from the value of the positions below it that results from each different legal move. If the MAX player is to move in some position, the value of that position is the maximum of the values of the positions that result from each legal move. Similarly, if the MIN player is to move in a given position, the value of that position is the minimum of the values of the positions that result from each legal move. By backing these values up the tree, one can compute the value of the current game state and make one move toward the position that gave rise to this value.

Figure 2 shows an idealized four-level game tree, where the square nodes represent the game states where MAX is to move, and the circle nodes represent states where MIN is to move. The numbers at the bottom level of the tree come from the heuristic evaluation function, and the numbers at the interior nodes are computed from the nodes immediately below them by the minimax rule. The move recommended by this procedure is to the left child of the root node. A much more efficient version of this algorithm, known as alpha–beta pruning (Knuth and Moore, 1975), is used in practice.

Constraint-Satisfaction Problems

A classic *constraint-satisfaction problem* is the Eight-Queens problem. The task is to place eight queens on a standard 8×8 chessboard so that no two queens attack each other on the same row, column, or diagonal. Figure 3 shows one solution to the Eight-Queens problem. In a constraint-satisfaction problem, the task is not to find a sequence of moves, but to identify a state that satisfies a set of constraints. The standard

						Q	
	Q						
			Q				

Figure 3 A solution to the Eight-Queens problem.

algorithm for these problems is known as *backtracking*. We systematically place queens on the board one at a time, one per row, so that no two queens on the board are in the same column or diagonal. If we get to a state in which no additional queens can be placed without attacking an existing queen, and all the queens have not yet been placed, we backtrack by moving the last queen that was placed to the next column where it does not attack any of the previously placed queens. The algorithm continues until one solution is found, all solutions are found, or it is determined that no solutions exist, which is the case with the two and three queens problems.

Artificial Intelligence: Connectionist and Symbolic Approaches

Ron Sun, Rensselaer Polytechnic Institute, Troy, NY, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article describes the two competing paradigms of artificial intelligence: connectionist and symbolic approaches. Each paradigm has its strengths and weaknesses. No single existing paradigm currently can fully address all major issues concerning intelligence and cognition. This condition indicates the need to integrate these existing paradigms.

Perhaps the most significant feature of current computational research on intelligence and cognition is the coexistence of a number of vastly different and apparently conflicting paradigms that compete for the attention of the research communities. Artificial intelligence (AI) aims to reproduce human-level intelligence (and even beyond) in computational forms. Various computational paradigms have been developed or utilized to understand intelligence and cognition based on different theoretical and practical considerations.

This article describes two major competing paradigms of AI: the connectionist and the symbolic approaches. Brief analysis of each paradigm is provided. As a result of the analysis of their respective strengths and shortcomings, possible integration of the two is also discussed.

The Two Paradigms

The two main competing paradigms in AI can be summarized as follows:

1. The traditional symbolic paradigm (Newell and Simon, 1976). The field of AI, since its inception, has been conceived mainly as the development of computational models that capture intelligent behaviors on the basis of symbol manipulation. Computation in such models is performed based on explicit representations with symbols organized in some specific ways. Aggregate information is explicitly represented with aggregate structures that are constructed from syntactic combinations of constituent symbols.
2. The more recent connectionist paradigm (Rumelhart and McClelland, 1986; Grossberg, 1982). The emergence of the connectionist paradigm largely resulted from dissatisfactions with computational models centered on symbol manipulation, especially with their inability to deal with flexible and robust information processing in a computationally efficient manner, which is needed to capture human-level intelligence. The connectionist paradigm leads to massively parallel models that consist of a large number of simple and relatively uniform processing elements interconnected with extensive links – that is, artificial neural networks and their various generalizations. In many connectionist models, representations are distributed throughout a large number of processing elements (in correspondence with the structure of such models). Sometimes, the constituent symbolic structures of aggregate information are embedded in a network and are hard to identify. Because of their massively parallel nature, such models often are good at flexible and robust information processing and have shown promise at dealing with some issues of human intelligence and cognition that have been difficult for the symbolic paradigm.

Thus far, no single existing paradigm can fully address all the issues and problems in the computational study of intelligence and cognition. Each paradigm has its strengths and weaknesses, and each excels at certain tasks while falling short at some others. This situation indicates the need to integrate these existing paradigms (see Section Hybrid models).

Symbolic AI

The *physical symbol system hypothesis* introduced by Newell and Simon (1976) articulated the tenets of symbolic AI. They defined a *physical symbol system* as follows:

> A physical symbol system consists of a set of entities, called symbols, which are physical patterns that can occur as components of another type of entity called an expression (symbol structure). Thus a symbol structure is composed of a number of instances (or tokens) of symbols related in some physical way (such as one token being next to another) (p.116).

They further claimed that symbols can designate arbitrarily: 'a symbol may be used to designate any expression whatsoever;' 'it is not prescribed a priori what expressions it can designate.' 'There exist processes for creating any expression and for modifying any expression in arbitrary ways.' Based on that, they concluded: 'A physical symbol system has the necessary and sufficient means for general intelligent action,' which is the well-known *physical symbol system hypothesis*.

The physical symbol system hypothesis has spawned (and was used to justify) enormous research effort in traditional AI (and in cognitive science). This approach (classical symbolism) typically uses discrete symbols as primitives and performs symbol manipulation in a sequential and deliberative manner.

Representation and Search

Two fundamental ideas that have played central roles in symbolic AI are search and representation, which originated in the earliest days of AI.

Let us first discuss the idea of search space. In any problem to be tackled with AI, there is supposed to be a space of *states*, each of which describes a step in problem solving (inference). *Operators* can be applied to reach a new state from a current state. Search techniques adopted from the early days of AI include depth-first search and breadth-first search. In depth-first search, from the current state, the system examines one alternative (a path) at a time by applying one of the operators to the current state, which leads to a new state. From the new state, the same process then is repeated, until it reaches a goal state or hits a dead-end at which point no operator can be applied. In the latter case, the system backs up to a previous state and tries a different alternative. In breadth-first search, however, from the current state, the system examines all alternatives (paths) by applying all the applicable operators. Such exhaustive search techniques are inefficient. To speed up search, many heuristic search algorithms have been proposed and applied to many domains. The idea of search space has been used in all areas of AI, including in problem solving, natural language processing, robotics, vision, knowledge representation/reasoning, and machine learning (see Russell and Norvig, 2010, for more details regarding search).

Another important idea in symbolic AI is representation. Representation is based on the belief that knowledge should be expressed in an internal form that facilitates its use, corresponding to the requirement of the task to be handled and mirroring the external world in some way. A variety of symbolic representational forms have been developed over the years, and most of them are used in conjunction with search algorithms. One of the earliest representational forms is rule-based reasoning, in which discrete rules are used to direct search (inference). Rules are composed of conditions, which specify the applicability of a rule, and conclusions, which specify actions or outcomes. Rules are modular: ideally, each rule can be added to or deleted from a system, without affecting the other parts of the system (however, modularity may negatively affect dynamic interaction).

A popular form of rule-based reasoning is the production system, which evolved from psychological theories that emerged in the 1960s and 1970s. A production system consists of (1) a production rule base (for storing all the rules), (2) a working memory (for storing initial, intermediate, and final results), and (3) a control structure (for coordinating the running of the system). The system can perform either forward chaining (from conditions to actions) or backward chaining (from actions to conditions).

Formal logics constitute an alternative to production systems for rule-based reasoning, as advocated by John McCarthy (McCarthy, 1968). Logics are relatively simple, formally defined languages capable of expressing rules in a rigorous way. Logical inference is performed in formally defined ways that guarantee the completeness and soundness of the conclusions, which can be carried out using a variety of algorithms beyond forward and backward chaining. Formal logics (and most production systems) are restrictive: one needs to have all conditions precisely specified to perform one step of inference. Thus, they often are unable to deal with partial, incomplete, or approximate information. There is also no intrinsic way for handling similarity-based reasoning (Sun, 1994).

Another type of representation aims to capture the aggregate *structures* of knowledge (instead of dispersing such structures as in production systems). Knowledge can be organized in structured chunks, each of which is centered on a particular entity or concept, and each can contain, or be contained in, other chunks. Each chunk contains all the pieces of information regarding a certain entity as well as their interrelations. For instance, a *frame* (as proposed by Marvin Minsky) represents a concept in terms of its various attributes (slots), each of which has a name (label) and a value. By organizing knowledge in frames, all the relevant pieces of information can be accessed in a structured way. A *semantic network* (as proposed by Ross Quillian) consists of a set of nodes, each of which represents a particular concept, and labeled links, each of which represents a particular relation between nodes. Semantic networks also allow efficient access of knowledge, albeit in a different way, by following links that go from one concept to all the others that have a particular relation to the original one, by, for example, 'spreading activation.' *Scripts* (proposed by Roger Schank and associates) are used to represent prototypical event sequences in stereotypical situations, for example, eating in a restaurant. In such a situation, there is an almost fixed sequence. Scripts help with the recognition and handling of these sequences. The shortcomings of these types of representations include (1) structures often need to be determined a priori and hand coded, (2) they usually are fixed and cannot be changed dynamically, and (3) they may become too costly and unwieldy to capture the full extent of complex real-world situations.

Some developments in the symbolic paradigm aim to remedy some of the problems with traditional symbolic representation, especially those with logic-based approaches as discussed earlier. These extensions include, for example, default logic, among many others. *Default logic* is proposed to capture default reasoning: it deals with beliefs based on incomplete information, which might be modified or rejected later based on subsequent observations. Such logics have shortcomings, including the lack of capabilities for dealing with (1) approximate information, (2) inconsistency, and (3) reasoning as a complex, interacting process (Sun, 1994). Thus, they are somewhat deficient from the standpoint of capturing human reasoning. For an overview of these models, see Davis (1990).

In a different vein, Zadeh proposed *fuzzy logic* (see Zadeh, 1988), primarily to capture vagueness or approximate information in linguistic expressions, such as 'tall' or 'warm,' which have no clear-cut boundaries. The basic idea is as follows: for each concept, a set of objects satisfying that concept to various degrees form a subset, namely, a fuzzy subset. This fuzzy (sub) set contains as its elements pairs consisting of an object and its grade of membership, which represents the degree to which it satisfies the concept associated with the set. A fuzzy logic therefore can be constructed with which one can reason about the fuzzy truth values of concepts.

The *probabilistic approach* (especially the Bayesian network approach) treats beliefs as probabilistic events and utilizes probabilistic laws for belief combinations (Pearl, 1988). Human reasoning, however, may not always conform to the assumptions and the laws of probability theory, in part because of the complexity of the formal theory. In addition, it is not always possible to obtain accurate probability measures in practice.

Symbolic Learning

Learning is a major aspect of AI, as well as being important for cognitive science and other related fields. Although sophisticated representations have been developed for symbolic AI, learning has been difficult. This is in part due to the fact that, from its inception, symbolic AI has been centered on representation, not learning.

Nevertheless, there have been some significant developments of symbolic learning, especially since the late 1980s. The majority of work in symbolic machine learning focuses on 'batch learning.' Typically, the learner is given all the instances, positive or negative, before learning starts. Most of these algorithms handle the learning of concepts with simple rules or decision trees (Quinlan, 1986). They typically involve (1) a division of all the instances into mutually exclusive or overlapping classes (i.e., clustering), or (2) the induction of a set of classification rules describing the makeup of a concept (Michalski, 1983; Quinlan, 1986).

Some symbolic learning algorithms have been extended to deal with noisy or inconsistent data and to deal with incremental learning. In addition, inductive logic programming tries to induce more powerful first-order rules from data. Some reinforcement learning algorithms also have handled dynamic sequences, which necessarily involve temporal credit assignment (i.e., attributing a success or failure to some preceding steps; Sutton and Barto, 1998). Probabilistic learning algorithms also have been developed. Many of these more recent learning methods, however, are more numerical than symbolic.

Criticisms

Although the symbolic paradigm dominated AI and cognitive science for a long time, it has received criticisms from various sources (e.g., from Rodney Brooks, John Searle, and Hubert Dreyfus; see Dreyfus and Dreyfus, 1986). The criticisms focused largely on the disembodied abstractness of this approach, especially in relation to interacting with the world. Some, such as John Searle, emphasized the importance of biological substrates of intelligence. Others have more specific criticisms some of which were identified earlier.

Connectionist AI

In the 1980s, the publication of the parallel distributed processing book (Rumelhart et al., 1986) started the so-called connectionist revolution in AI and cognitive science. The basic idea of using a large network of extremely simple units to tackle complex computation seemed completely antithetical to the tenets of symbolic AI and has met both enthusiastic support (from those disenchanted by symbolic AI) and acrimonious attacks (from those who believed in the symbolic AI agenda). Even in the twenty-first century, we can still feel, to some extent, the divide between connectionist AI and symbolic AI, although hybrids of the two paradigms and other alternatives have flourished. Much of the controversy, however, was the result of misunderstanding, overstatement, and terminological differences.

Connectionist models are believed to be a step in the direction toward capturing the intrinsic properties of the biological substrates of intelligence in that they have been inspired by biological neural networks and seem to be closer to neurobiological processes (Grossberg, 1982). They often are capable of dealing with incomplete, approximate, and inconsistent information as well as generalization.

Connectionist Learning

Connectionist models excel at learning: Unlike the formulation of symbolic AI, which focused on representation, connectionist models have very much been about learning. Learning in connectionist models generally involves the adjustment of weights in a large network of units, so that complex computations can be accomplished through activation propagation through these weights (although there have been other types of learning algorithms, such as constructive learning and weightless learning). The weight tuning usually is based on gradient descent or its approximations for gradually minimizing an error function. The best known of such learning algorithms is the backpropagation algorithm (Rumelhart et al., 1986).

Connectionist learning algorithms have been devised for (1) supervised learning, similar in scope to aforementioned symbolic learning algorithms for classification rules but resulting in a trained network instead of a set of rules; (2) unsupervised learning, similar in scope to symbolic clustering algorithms, but without the explicit use of rules; and (3) reinforcement learning, either implementing symbolic reinforcement learning methods or adopting uniquely connectionist ones.

Connectionist learning has been applied to learning some forms of symbolic knowledge. For example, Pollack (1990) used the standard backpropagation algorithm to learn tree structures, through repeated applications of backpropagation at different branching points of a tree, in an auto-associative manner (known as recurrent auto-associative memory). Because trees are a common symbolic form, this approach is applicable to learning many symbolic structures. Similarly, Giles and Gori (1998) used backpropagation to learn finite-state automata, another common symbolic structure. Connectionist learning algorithms combine the advantages of their symbolic counterparts with the connectionist characteristics of being noise and fault tolerant and being capable of generalization. For an overview of both symbolic and connectionist learning, see Mitchell (1997).

Connectionist Knowledge Representation

Although it is relatively difficult to develop complex, structured representations in connectionist models (compared with symbolic models), there have been some significant developments of connectionist knowledge representation. Many so-called 'high-level' connectionist models have been proposed that employ representations that are comparable to, and sometimes even surpass, symbolic representations, and these models remedy certain problems of traditional representation methods. For an overview of connectionist knowledge representation, see Sun and Bookman (1995).

Let us look into some of these developments in more detail. First, logics and rules can be implemented in connectionist models in a variety of ways. For example, in one type of

connectionist system, inference is carried out by constraint satisfaction by minimizing an error function. The process, however, is slow. Another type of system, as proposed by a number of researchers in the early 1990s, uses more direct means by representing rules with links that directly connect nodes representing conditions and conclusions, respectively, and inference in these models amounts to activation propagation (e.g., Shastri and Ajjanagadde, 1993). They thus are more efficient. They also deal with the so-called variable binding problem in connectionist networks. Advanced logics that go beyond classical logic also can be incorporated into connectionist models (see, e.g., Sun, 1994).

Aggregate information can be represented in connectionist models. A system developed by Miikkulainen and Dyer (1991) encodes scripts by dividing input units of a backpropagation network into segments, each of which encodes an aspect of a script in a distributed fashion. The system is capable of dealing with incomplete (missing) information, inconsistent information, and uncertainty. In localist alternatives, a separate unit is allocated to encode an aspect of a frame (Sun, 1994).

Search, the means of utilizing knowledge in representation, may be employed or embedded in connectionist models. Either a search can be conducted through a settling or error minimization process (as discussed earlier), or a search can be conducted through a massively parallel activation propagation. Symbolic search requires global data retrieval and thus is costly in terms of time. Global error minimization (as in some connectionist models) is also time consuming. Local computation in connectionist models is a viable alternative. Knowledge may be stored in a network connected by links that capture search steps (inferences) directly. Search amounts to activation propagation by following links (similar to semantic networks in a way), without global control.

The advantage of connectionist knowledge representation is that such representation can not only handle symbolic structures in some ways but also goes beyond them by dealing with incompleteness, inconsistency, uncertainty, approximate information, and partial match (similarity) and by treating reasoning as a complex dynamic process. Developing representation in highly distributed media, such as connectionist networks, is inherently difficult.

Hybrid Models

Given the different strengths of connectionist and symbolic systems, it seems possible that combining them would be a promising avenue for developing more robust, more versatile, and more powerful systems. Research on such systems has been slowly but steadily growing. A great deal of developments have led to hybrid connectionist-symbolic systems.

The relative advantages of connectionist and symbolic models have been amply argued for – see, for example, Waltz and Feldman (1988) and Sun and Bookman (1995). The computational advantage of the combination is thus relatively easy to justify. Naturally, we want to take advantages of both types of models and their synergy (for additional justification, see Dreyfus and Dreyfus, 1986; Sun, 1994).

Many issues need to be addressed in developing hybrid connectionist-symbolic systems. These issues concern architectures, learning, and various other aspects of hybrid models. First, hybrid models likely involve a variety of different types of processes and representations. Multiple heterogeneous mechanisms interact in likely complex ways. We need to consider ways of structuring these different components; in other words, we need to consider *architectures*, which thus occupy a prominent place in this line of research. Second, although purely connectionist models, which constitute part of any hybrid system, are known to excel in their learning abilities, hybridization makes it more difficult to perform learning. In a way, hybrid systems inherit the difficulty with learning from the symbolic side and mitigate to some extent the advantage that (purely) connectionist models have in terms of learning.

Architectures and Representations

We may divide hybrid systems into two broad categories: *single-module* and *multimodule* architectures. Among single-module models, along the representation dimension, there can be the following types (Sun and Bookman, 1995): symbolic, localist (with one distinct node for representing each concept; see, e.g., Shastri and Ajjanagadde, 1993), and distributed (with a set of nonexclusive, overlapping nodes for representing each concept; see, e.g., Pollack, 1990). Among multimodule systems, we can distinguish between *homogeneous* and *heterogeneous* systems. Homogeneous systems are similar to single-module systems, except they contains several copies of the same structure, each of which can be used for processing different inputs, or the same set of inputs, to provide redundancy for various reasons.

Heterogeneous multimodule systems are more complex and interesting. This category constitutes the true hybrid systems. As an example, CONSYDERR (Sun, 1994) belongs to this category. It consists of two 'levels' (modules): the top level is a network with localist (symbolic) representation, and the bottom level is a network with distributed representation; concepts and rules are represented diffusely in the bottom level by sets of feature units. This is a similarity-based representation in which concepts are 'defined' in terms of their similarity to other concepts in these representations. The localist network is linked with the distributed network by connecting each node in the top level representing one concept to all the feature nodes in the bottom level representing the same concept. Through a three-phase interaction between the two levels, the model is capable of both rule-based and similarity-based reasoning, dealing with incomplete, inconsistent, and approximate information, and accounts for a large variety of seemingly disparate patterns in human reasoning.

A variety of distinctions can be made here. For instance, a distinction can be made in terms of representations of constituent modules. In heterogeneous multimodule systems, there can be different combinations of different types of constituent modules. For example, a system can be a combination of localist modules and distributed modules (as in CONSYDERR), or it can be a combination of symbolic modules and connectionist modules (either localist or distributed).

Another distinction can be made among heterogeneous multimodule systems in terms of the *coupling* of modules: a set of modules can be either loosely coupled or tightly coupled. In loosely coupled situations, modules communicate with each

other, primarily through message passing, shared memory locations, or shared files. Such loose coupling enables some loose forms of cooperation among modules. One form of cooperation is in terms of pre- and postprocessing versus main processing: while one or more modules take care of pre- and postprocessing, such as transforming input data or rectifying output data, a main module focuses on the main part of the task. Another form of cooperation is through a master-salve relationship: while one module maintains control of the task at hand, it can signal other modules to handle some specific aspects of the task. For example, a symbolic expert system, as part of a rule, may invoke a neural network to perform a specific classification. Yet another form of cooperation is the equal partnership of multiple modules. In this form, the modules (the equal partners) can consist of (1) functionally complementary processes, (2) multiple functionally equivalent but representationally different processes, or (3) multiple differentially specialized and heterogeneously represented experts each of which constitutes an equal partner in accomplishing a task.

In tightly coupled systems, on the other hand, the constituent modules interact through multiple channels or may even have node-to-node connections across two modules (such as CONSYDERR in which each node in one module is connected to a corresponding node in the other module; Sun, 1994). A variety of forms of cooperation among modules exist, similar to loosely coupled systems.

Learning

Learning, which can include (1) learning the content (knowledge) in a hybrid model or (2) learning and developing the structure of the model itself, is a fundamental issue that is clearly difficult. Learning is indispensable, however. Over the years, some progress on learning has been made. Although some researchers have tried to extend connectionist learning algorithms to learn complex symbolic representations, others have incorporated symbolic learning methods. For example, Sun (2002) developed CLARION, in which symbolic knowledge is extracted online from a reinforcement learning connectionist network and is used, in turn, to speed up connectionist learning and to facilitate transfer. The work showed not only the synergy between connectionist and symbolic learning but also that symbolic knowledge can be learned autonomously online, from subsymbolic knowledge, which is useful in developing autonomous agents.

Learning methods that may be applied to hybrid systems include gradient descent and its many variations (extending typical connectionist learning algorithms), expectation-maximization and its many instantiations (including hidden Markov model algorithms), search algorithms, probabilistic algorithms, evolutionary algorithms, and heuristic methods (such as decision trees or rule induction; see Mitchell, 1997). Some of these methods may be combined with others (as in Sun, 2002), which likely results in enhanced learning. A variety of other learning approaches also are being proposed, including many rule extraction or insertion algorithms.

There is a sense that future advance in this area depends on the development of new learning methods for hybrid systems and the integration of learning and complex representations. As mentioned (see Sun, 2002), symbolic representation and reasoning may well emerge from subsymbolic processes through learning, and thus an intimate and synergistic combination of symbolic and subsymbolic learning processes should be pursued.

Discussion

Despite the diversity of the connectionist, symbolic, hybrid, and other approaches discussed thus far, there is an underlying common theme: bringing together symbolic and connectionist models to achieve a synthesis of the two seemingly different paradigms.

Without doubt, we need to invest substantial efforts in continuing analyzing and exploring various paradigms, especially the symbolic paradigm and the connectionist paradigm, to reveal their respective strengths and limitations, as well as underlying assumptions, which can lead to better understanding and more rapid development of the AI field. Although significant advances have been achieved so far, this process is still on-going, and it appears that it will not be concluded until a better understanding is achieved of the nature of intelligence in computational terms.

In the meantime, it is an appealing idea that representation and learning techniques from both symbolic models and connectionist network models shall be brought together to tackle problems that neither type of model alone can apparently handle very well.

In particular, one such problem is the modeling, simulation, and explanation of human cognition, which requires dealing with a variety of psychological capacities. Several researchers (e.g., Dreyfus and Dreyfus, 1986; Sun, 1994, 2002) have argued consistently that cognition is multifaceted and better captured with a combination of symbolic and connectionist methods. Many approaches and frameworks reviewed also share the belief that connectionist and symbolic methods can be integrated usefully, and such integration may lead to significant advances in our understanding of cognition. Some probabilistic models may be seen in this light. Hybridization indeed may be a theoretically sound approach, in addition to being a practically expedient approach.

Artificial Intelligence: Genetic Programming

Wolfgang Banzhaf, Memorial University of Newfoundland, St. John's, NL, Canada

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article discusses the method of genetic programming by first setting it into the context of artificial intelligence and the theory of evolution, and then by describing its mechanisms and the progress of the field in recent years. The second part of this article explains applications of the method. The article starts with a general discussion, then points out some of the striking results of the method, and finally turns to the area close to social and behavioral sciences. The article concludes with a discussion of methodological issues and perspectives.

Introduction

Genetic programming (GP) describes a research area within the field of artificial intelligence (AI) that deals with the *evolution* of computer code. The term *evolution* refers to an artificial process analogous to the natural evolution of living organisms according to Darwin's theory of evolution by natural selection (Darwin, 1859). The process has been abstracted and stripped of most of its intricate details. The resultant algorithms then yield approximate solutions to problems in machine learning or induce precise solutions in the form of grammatically correct (language) structures for the automatic programming of computers.

GP is part of a growing collection of evolutionary algorithms that apply heuristic search principles inspired by natural evolution to a variety of different problem domains, notably, parameter optimization. Genetic algorithms, evolutionary programming, evolutionary strategies, and differential evolution are other branches of the area of evolutionary algorithms that mostly find applications as optimization techniques. The major distinction between GP and these other areas of evolutionary algorithms is that GP handles active components like symbolic expressions, computer instructions, or other tools to control behavior, as opposed to simple parameters. Additionally, GP is able to develop its own representation of a problem by allowing variable complexity of its individuals.

All evolutionary algorithms follow Darwin's principle of differential natural selection in a variation - selection loop Figure 1. This principle states that the following preconditions must be fulfilled for evolution to occur via (natural) selection:

- Entities called individuals form a population. These entities can reproduce or can be reproduced.
- There is heredity in reproduction, that is to say that individuals produce similar offspring.
- In the course of reproduction, variety affects the likelihood of survival and therefore of reproducibility of individuals.
- Finite resources cause individuals to compete. Because of overreproduction, not all individuals can survive the struggle for existence. Differential natural selection exerts a continuous pressure toward improved individuals.

Mechanisms behind GP

GP works with a population of computer programs that are executed or interpreted to judge their behavior. Usually, a scoring operation called fitness measurement is applied to the outcome of the behavior of a program individual. For instance, the deviation between the quantitative output of a program and its target value (defined through an error function) could be used to judge the behavior of the program. This is a straightforward procedure if the function of the target program can be clearly defined. Results may be defined as side-effects of a program, such as consequences of the physical behavior of a robot controlled by a genetically developed program. Sometimes, an explicit fitness measure is missing, for instance, in a game situation, and the results of the game (winning or loosing) are taken to be sufficient scoring for the program's strategy. The general approach is to apply a variety of programs to the same problem and to compare their performance relative to each other.

The outcomes of fitness measurement are used to select programs. There are a number of different methods for selection, both deterministic and stochastic. Selection determines (1) which programs are allowed to survive (overproduction selection), and (2) which programs are allowed to reproduce (mating selection). Once a set of programs has been selected for further reproduction, the following operators are applied: reproduction, mutation, and crossover.

Reproduction simply copies an individual to an offspring population (the next generation), *mutation* varies the structure of an individual under control of a random number generator, and *crossover* mixes the structures of two (or more) programs to generate one or more new programs for the offspring population. Additional variation operators are applied in different applications. Most of these contain problem knowledge in the form of heuristic search recipes that are adapted to the problem domain.

In this way, fitness advantages of individual programs are exploited in a population to lead to better solutions. In GP, as well as in other evolutionary algorithms, differential selection can be realized in a number of different ways.

The simplest approach is a generational selection scheme called fitness proportional or roulette wheel selection. In roulette wheel selection, the fitness of all individuals in the population is summed up. The fitness f_i of each individual i is then normalized by the sum of all fitness values found, and this normalized value determines its probability of being selected for reproduction, mutation, and crossover. Thus, $p_i = f_i/\sum_j f_j$. Based on the stochasticity of random events, fitness proportional selection sometimes allows weaker individuals to succeed in reproduction.

Figure 1 The variation selection loop of GP.

Another selection method is called tournament selection. In tournament selection, a subset of individuals in the population is drawn randomly, and their fitness is compared with one another. The individuals with higher fitness are allowed to replace (directly as in reproduction, or with a variation as in mutation and crossover) the individuals with lower fitness. Normally, tournament selection is done with a minimum amount of $k = 4$ individuals, which carries the lowest selection pressure. Larger tournaments, however, have been used in the literature, up to the extreme of holding tournaments among the whole population, at which point the selection scheme is called truncation selection.

Ranking selection is another selection scheme introduced to address some weaknesses of fitness proportional selection. Each individual is assigned a rank in the population, and selection proceeds either by a linearly or by an exponentially associated probability, based on the rank of an individual. A detailed comparison of different selection schemes is given in Blickle and Thiele (1996).

A key effort in GP is the definition of the fitness measure. Sometimes the fitness measure has to be iteratively improved for the evolved solutions to actually perform the function for which they were intended. The entire process can be seen in close analogy to breeding animals. The breeder has to select those individuals from the population that carry the targeted traits to a higher degree than others.

Turing (1950), Friedberg (1958), and Samuel (1963) suggested ideas similar to GP in the early days of AI, but their results were quite limited at the time. It was only after other techniques in evolutionary algorithms had been developed successfully that GP emerged. Earlier work concerned *genetic algorithms* by Holland (1975), *evolution strategies* by Rechenberg (1974) and Schwefel (1981), and *evolutionary programming* by Fogel et al. (1966). These methods have been applied successfully to a wide spectrum of problem domains, especially in optimization. It was unclear for a long time, however, whether the principles of evolution could be applied to computer code, with all its dependencies and structural brittleness. Negative results from early experiments seemed to indicate that evolution of computer code was not possible. Successes were all realized in the area of constraint optimization (Michalewicz, 1996), where methods were made available to deal with structural brittleness. These methods found their way into programming subsequently and gave rise to the new field of GP (Koza, 1992).

Progress and State-of-the-Art

In his seminal work of 1992, Koza established the field of GP by arguing convincingly that manipulation of structures of symbolic expressions is possible with evolutionary algorithms and that the resulting technique would have a wide variety of applications. In subsequent years, the field experienced both broadening and deepening (Banzhaf et al., 1998). Many different representations for GP were studied, among them other generic data structures, such as sequences of instructions (Figure 2) or directed graphs, as well as more exotic data structures, such as memory stacks or neural networks. In the twenty-first century, different approaches are considered to be GP, from the evolution of expression trees to the evolution of arbitrary structures. The overarching principle is to subject structures with variable complexity to forces of evolution by applying mutation, crossover, and fitness-based selection. The results must not necessarily be programs, but instead they could be descriptions for designs (like structures of bridges) or other manipulatable elements.

An ever-present difficulty with GP is that the evolution of structures of variable complexity often leads to large structures with considerable redundancy. Notably, it was found that variable complexity often leads to inefficient and space consuming code. It was subsequently recognized that the evolutionary forces exerted a pressure toward more complex solutions, parts of which could be removed after evolution without doing any harm to the behavior of the evolved solution. By drawing an analogy from biological evolution of genomes, this phenomenon originally was called 'code bloat,' 'intron growth,' or 'growth of ineffective code.' It was found that code growth is not the only unintended result of evolutionary processes, but it has been the most examined emergent phenomenon to date (Nordin et al., 1997). At least three different influences are at work promoting the growth of complexity during evolution. The most important influence has to do with the protection effect of redundant code if it is subjected to the action of crossover or mutation. Redundant code is more resistant to

Figure 2 The primary operations of GP, mutation and crossover, are applied here to programs represented by sequences of instructions. The instructions are coded as integer numbers that allow for easy manipulation by access to these numbers.

crossover and mutation and allows its carrier solution to survive better than other individuals that do not possess this redundancy (Nordin and Banzhaf, 1995). Removal bias in crossover operations (Soule and Foster, 1998) describes the fact that code can grow to infinity from any size; another explanation is that it only can be reduced to zero for a particular size. Finally, a genetic drift toward larger solutions (Langdon, 1997) has been named as an important influence.

Over the past decade, the relation between robustness of organisms and their evolvability has been under intense study in biology (Wagner, 2005). A seeming paradox between these two features frequently found in nature has been resolved. A key aspect of robustness was found to be neutral evolution – that is, the capability of evolution to change genotypes without changes to phenotypes of individuals. This capability has been known for decades and previously had been discovered to be an important process in evolution, called neutral evolution (Kimura, 1983). The understanding of neutrality led to new mathematical models like the idea of neutral networks (Forst et al., 1995). A transfer of these ideas into GP is currently under way (Hu et al., 2011).

Although the theory of genetic algorithms has been well established, theoretical progress in GP has been more difficult to achieve because GP works with variable complexity and multiple fitness cases for fitness scoring. Many researchers are working to produce results for GP by gleaning information from the research on genetic algorithms. The schema theory of genetic algorithms (Goldberg, 1989; Vose, 1999) has been a primary target of knowledge transfer. In the meantime, a number of different schema theorems have been formulated for GP, and theory has progressed substantially (Poli et al., 2010).

When analyzing search spaces of programs, it was realized that their size is many orders of magnitude larger than search spaces of combinatorial optimization problems. A typical size for a program search space might be $10^{100,000}$, as opposed to a typical search space for a combinatorial optimization problem of the order of 10^{100}. Although this might be a discouraging interpretation for search mechanisms, it also was realized that the solution density in program spaces is, above a certain threshold of complexity, constant with changing complexity (Langdon, 1999). In other words, there are proportionally many more valid solutions in program spaces than in the spaces of combinatorial optimization problems.

Applications

The main application areas of GP are as follows (from narrow to wide) (Banzhaf et al., 1998):

- Computer science
- Science
- Engineering
- Arts and entertainment

In computer science, the development of algorithms has been a focus of attention. By being able to manipulate symbolic structures, GP is one of the few heuristic search methods for algorithms. Sorting algorithms, caching algorithms, compression algorithms (Kattan and Poli, 2011), random number generators, and algorithms for automatic parallelization of code (Ryan, 2000), to name a few, have been studied. The spectrum of applications in computer science spans from the generation of proofs for predicate calculus to the evolution of machine code for accelerating function evaluation. The general tendency is to automate the design process for algorithms of different kinds. Recently, the process of debugging code, that is, the correction of errors, has been added to the list of applications (Forrest et al., 2009).

Typical applications in science are modeling and pattern recognition. Modeling certain processes in physics and chemistry with the unconventional help of evolutionary creativity supports research and understanding of the systems under study. Pattern recognition is a key ability in molecular biology and other branches of biology, as well as in science in general. In this context, GP has delivered first results that are competitive if not better than human-generated results.

In engineering, GP is used in competition or cooperation with other heuristic methods such as neural networks or fuzzy systems. The general goal is again to model processes, such as production plants, or to classify results of production. In recent years, design in engineering has gained some prominence (Lohn et al., 2004). Control of manmade apparatus is another area in which GP has been used successfully, with process control and robot control being the primary applications.

In arts and entertainment, GP is used to evolve realistic animation scenes and appealing visual graphics. It has been used to extract structural information from musical composition to model the process so that automatic composition of music pieces becomes possible.

Many of these problems require a huge amount of computational power on the part of the GP systems. Parallel evolution has been a key engineering aspect of developments in GP. As a paradigm, GP is well suited for a natural way of parallelization. With the advent of inexpensive parallel hardware, in recent years – in particular through graphics processing units (Banzhaf et al., 2009) – a considerable proliferation of results is expected from GP systems.

Human-Competitive Results of GP

In the past decade, a substantial number of results have been published in various fields that claim to have produced human-competitive results by applying GP as a problem-solving method.

These claims are based on a comparison between the presently best-known human solutions to a problem and their respective counterparts produced by GP. Applications are from areas like quantum computing algorithms, analog electrical circuit design and other mechanical and electrical designs, game-playing applications, finite algebras and other mathematical systems, bioinformatics and other scientific pattern recognition problems, reverse engineering of systems, and empirical model discovery. Some of the similarities of these successes were summarized by Koza (2010) as follows:

- Usually, a large amount of computational power has to be invested to gain human-competitive results from GP runs.
- Most times, a dedicated representation for the solution, known to be efficient by the specialist, has been applied to

allow the full power of expression of solutions to be born on the problem.
- The GP system has been equipped with dedicated growth or development operators such that the adaptation of complexity of a description can be achieved smoothly.

Because of the ability of the human mind to quickly grasp the recipes of problem solution that an artificial system has applied, the question remains open whether solutions found by a GP system will remain qualitatively better than solutions discovered by human.

Evolution, Development, and Learning

The relation between evolution and development has been studied for decades in biology (West-Eberhard, 2003). It was found that the time-dependent process of gene expression and gene regulation through both internal and external cues is the mechanism by which both processes can be unified (Ben-Tabou de Leon and Davidson, 2007). Some progress has been made in GP to couple evolution and development. The developmental approach in GP takes the form of a recipe that, upon its execution, generates a structure that is subjected to fitness tests (Spector and Stoffel, 1996). Thus, it is not the GP program itself that is tested, but the result of its execution.

Similar to the coupling between evolution and development, the coupling between development and learning was considered an important link for understanding the mechanisms of development and learning processes. Cognitive neuroscience has presented evidence for this coupling by finding that there are critical periods in development in which certain learning tasks are facilitated (and sometimes only possible) to take place. If the critical period is missed, learning success in a task is substantially reduced (Daw et al., 1978).

The coupling between development (or evolution) and learning has only recently been explored in GP. The problem is to clearly separate adaptations or fitness gains resulting from development or evolution versus those from learning. Its reason is the less stringent separation of time scales between evolution, development, and learning in GP systems. Although biological evolution can happen over many thousands or millions of years, development over the lifetime of an organism, and learning over phases of that lifetime, all three mechanisms are on similar time scales in GP and usually are tied into single runs of a GP system. In addition, in most GP systems, there is no notion of species (and their evolution). Rather, the entire population is essentially mixed and therefore belongs to one single species. Finally, the goal under the influence of evolution is behavior, the same entity usually associated with learning. First attempts have been made to examine learning as a separate task for which evolution and development have to provide the means (Harding et al., 2009), yet this area requires much more investigation.

Methodological Issues and Future Directions

Although GP has made great strides over the past two decades, a number of issues are still open and require continued investigation. The theory of GP has (Poli et al., 2010)

- succeeded in finding appropriate schema theorems that allow for an understanding of how the search space and the population representation interact,
- started to analyze Markov chain models of the search process dynamics, and
- found ways to characterize search spaces (difficulty, complexity) and relate them to the performance of GP systems.

In coming years, this theory is expected to make progress on the treatment of dynamical problems, proofs of convergence of the search algorithms, and in classifying problem spaces. On the practical side, research in GP will target the following (O'Neill et al., 2010):

- identifying appropriate representations for GP in particular problems,
- designing open-ended evolutionary systems with GP,
- addressing the problem of generalization in GP,
- establishing benchmarks for measuring and comparing GP performance, and
- pursuing modularity and scalability in GP.

Implementation of GP will continue to benefit in coming years from new approaches, including results from developmental biology and epigenetics. Application of GP will continue to broaden. Many applications focus on controlling behavior of real or virtual agents. In this role, GP may contribute considerably to the growing field of social and behavioral simulations. Genetic algorithms already have been found to be beneficial in optimizing strategies of social agents (Gilbert and Troitzsch, 1999). With its ability to adjust the complexity of a strategy to the environment and to allow competition between agents, GP is well positioned to play an important role in the study and simulation of societies and their evolution (Edmonds et al., 2007).

Abstract

Artisanal labor can be traced to the Neolithic Revolution, and can be found as a significant social group in every subsequent society, including contemporary societies of whatever economic level across the globe. For part of European history especially artisans gather in guilds, or associations of artisans, were especially important, and their significance is explained and underlined. In doing so the role of artisans in the preindustrial craft economy is compared with their role in industrializing and modern societies, underlining the very different ideas about skill entailed in each instance.

This article starts with a definition of artisanal labor and artisans. It presents the origins of artisans in the Neolithic Revolution, their social positions in ancient and medieval times as well as in early modern European corporate societies, and finally it discusses the redefinition of the artisan in eighteenth and nineteenth century class societies. In the second part, the article describes guilds as a particular type of artisanal association which existed almost everywhere in late medieval and early modern urban Europe, and it analyzes the role of artisanal and guild traditions in modern middle class and labor movements. A discussion of recent revisionism in guild and artisan historiography completes the article. This discussion stresses the dynamic and flexible character of the preindustrial craft economy, the perception of guilds as dynamic fields of social relations, the persistence of artisanal small-scale production in industrializing societies the gender dimension of the concept of the artisan, and, finally, the ambiguities of the concept of skill.

Definitions

Artisanal labor is a particular form of labor that has existed in most – if not all – human societies. Historically, it first appeared as nonagricultural production, and during the last 200 years primarily as small-scale or small-commodity production, in contrast to mass production and mechanized factory industry. The focus of the definition is on production, thus also distinguishing artisanal labor from economic activities such as commerce. Indeed, one cannot draw strict boundaries here. The English term 'trade,' for instance, has been in use for artisanal production as well as for commerce and exchange. Furthermore, artisanal labor is not necessarily limited to production, but also includes some activities that in modern economic thought are assigned to the tertiary or service sector. Artisan is a narrower concept than artisanal labor. While artisanal labor may be performed by men and women as one activity among many others, artisans can be defined as persons who specialize in artisanal labor and make their living mainly, if not exclusively, from this kind of work. There are some almost universal elements in the concept of the artisan: manual labor and the use of tools; specialization of labor, which connects the concept of the artisan with the concept of profession or occupation; skill and some kind of training as a precondition of skill; and work not for subsistence but for consumers or markets. Besides these universal elements, there are also some historically variable ones that fluctuate in accordance with broader social and economic change.

Artisans: Concepts and History

The origins of artisans are connected with social changes at the end of the Neolithic Revolution (see Work, History of) in approximately the fourth millennium BC. Foremost among these was the development of technology, above all in the fields of metallurgy, ceramics, and woodworking. This promoted specialization in the production of metals as well as in the fashioning of tools, weapons, and a growing number of practical implements. Second, the emergence of social stratification brought about increased demand for luxury goods by the upper classes, the production of which called for special training and particular skills. Third, there was the formation of urban cultures, especially in the Near East and the Mediterranean. Artisans were concentrated in cities, and it was here that the division of labor within artisanal production accelerated and specialized crafts and trades came into being. During the first millennium BC, dozens of different artisanal occupations emerged in the urban cultures of India, the Near East, and the Mediterranean.

The value assigned to labor in the crafts and trades and the social position of the artisan has been characterized by a high degree of ambivalence. In all societies in which work was held in low esteem, this applied to artisanal labor too. In European history, though, there is also a long tradition of valuing the work of artisans more highly than other forms of manual labor. Whereas in some non-European cultures, such as ancient China, artisans were assigned a lower social status than peasants, in the European tradition they enjoyed a relatively high level of prestige. In early ancient Greece, this was expressed in the myth of Prometheus the god of fire, pottery, and metallurgy. "In the eighth century BC the crafts of blacksmith, pottery, and weaving were considered in the same light as that of priests, bards and doctors (…). All these activities were called *technai*, that is, activities implying the use of secret processes, specialized knowledge based on long apprenticeship and an initiation ritual." (Godelier, 1980)

 http://dx.doi.org/10.1016/B978-0-08-097086-8.62012-3

Some crafts appeared as sacred in Gallic and Germanic mythology as well, and in the European Middle Ages, for instance, in the scale of social values in early Germanic law, artisans clearly had a higher rank than persons engaged in agricultural activities. "The craftsmen who forged the weapons for the aristocratic warriors (…); and the goldsmiths who decorated these weapons and created jewels for the women of these warriors (…) were important personages who upheld the prestige of technical skill" (Le Goff, 1980).

Artisans in Corporate Society

The urbanization process in twelfth- to fourteenth- century Europe strongly influenced the concept and the social standing of the artisan. Most importantly – and not at all usual for people working with their hands – artisans, as urban citizens, were freemen. In many English towns, for instance, completion of an apprenticeship entitled an individual to the freemanship of the respective town (which meant permission to take up residence, claim to social relief if the need arose, and often some form of political participation). The increasing division of labor in towns created a wide range of artisanal occupations, and the expanding guild system (cf guilds, see Section Guilds: Concepts and History) served as an institutional framework for training and work in these occupations. Both of these developments had consequences, which became basic to the concept of the artisan in the corporate societies of Europe from the late Middle Ages until the eighteenth century.

First, artisanal work – even if it was manual labor – was not simply regarded as labor. The negative connotations of labor (travail, hard work) as toil, pain, burden, or penitence were replaced by an understanding of artisanal labor as art. *Arts et métiers* (arts and trades) was the common French term used to group together all artisans (a generalizing term, which appeared in the sixteenth century). In eighteenth-century France, artisanal crafts were regarded as honorable because they were based not only on the 'effort of the body' but also on the "subtlety of the mind" (Sewell, 1980: p. 23). Second, by organizing in guilds or other associations, artisans had a recognized standing in society and the state. Whether they enjoyed royal privileges, municipal statutes, or the permission of the church to form a confraternity, all these defined them as a corps or as an estate (French: *état*; German: *Stand*). In both respects, inherent in the concept of the artisan was a sharp distinction vis-à-vis unskilled laborers.

The Ambiguous Journeyman

Traditionally, the concept of the artisan referred primarily to the master artisan – an independent craftsman, who ran his own workshop and casually or regularly employed a few hands. As head of the household, the master was part of the corporate structure and exercised domestic authority over his family and his workforce. On the other hand, the conception of the artisan also included different categories of employees. First, it referred to apprenticeship, which was understood as a period (and a social position) of training – generally, although not necessarily, connected with adolescence. In the late Middle Ages, there appeared a further group: artisans who had finished their apprenticeship but had not – or not yet – become masters. In English, the term journeyman (which stems not from the journey of the tramping artisan, but from the French word *jour* meaning day, and designating one who works and is paid by the day) became most widespread to describe this group. While the concepts of apprentice and master are relatively clear, the concept of the journeymen is fluid and ambiguous. On one hand, it refers to a life-cycle stage, as the completion of training, mainly by tramping a couple of years. From this perspective, journeymen were young, single men subject to the domestic authority of the master (when at work and not on the road), until they themselves became masters and householders. On the other hand, the concept of journeymen refers to wage laborers – often on a lifelong basis – having their own households and families. In practice, it is almost impossible to make a clear distinction between these two concepts and modes of life. Very roughly, the first type prevailed in small-scale production (bakers, tailors, and the like), the second in textiles (particularly where the craft was transferred into outwork or domestic industry) and in the building trades. Furthermore, the first seems to be more common in Central Europe, whereas the second is more familiar in the West, particularly in England. Many historians also believe that over the course of the late medieval and early modern history, the first type was gradually replaced by the second, but this is probably a far too general and too linear model (cf Reith, 1999). Generally, the relations between masters and journeymen included solidarity and moral community as well as conflict.

Redefinition of the Artisan in Class Society

In the emerging class societies of eighteenth- and nineteenth-century Europe, the concept of the artisan became redefined both in *petit bourgeois* and in proletarian terms. On one hand, the concept still focused on the independent master craftsman working in his own workshop with his own tools. Apprentices and journeymen were included in this concept as future or anticipated masters. On the other hand, the concept of the artisan increasingly referred to lifelong employed workers working in a wide range of economic settings – even in factories – but being distinguished from ordinary laborers by their common 'property of skill.' Artisans were "those who through apprenticeship or its equivalent had come to possess a skill in a particular craft and the right to exercise it" (Rule, 1987: p. 102).

In social theory, the first model became predominant. In Enlightenment philosophy as well as in political economy, the artisan began to be regarded as a countermodel to capitalism. Karl Marx conceptualized the artisan as a personification of a non- (or pre-) capitalist mode of production, which he called small-commodity production (*kleine Warenproduktion*). At the turn of the century, the German social scientist Werner Sombart regarded the artisan as the 'ideal type' of the precapitalist economic system, which, in his view, was characterized by empiricism and traditionalism (as opposed to rationality) and a lack of interest in accumulation and profit. This perspective became extremely powerful and shaped more or less completely the historical interpretation of the artisan.

In practice, however, in the economically advanced regions of Western Europe, most of the workmen who identified

themselves as artisans were in wage employment. Adam Smith in his 'Wealth of Nations' (1776) estimated that in England there were 20 men working for wages for everyone who was his own master (Rule, 1987: p. 103). Here, the artisan as a skilled workman became central to the self-image, identity, and rhetoric of the emerging working class. On the continent, and particularly in Germany, even in the mid-nineteenth century, the number of masters almost equaled the number of journeymen in the crafts and trades. Here, the concept of the artisan became synonymous with independent master craftsmen and their respective *petit bourgeois* political movements.

Guilds: Concepts and History

In Western history, both the concept and the practice of artisans are closely connected with guilds. Associations of artisans existed in many historic societies and cultures. For example, there is evidence of their existence in classical India, ancient Rome, Tokugawa Japan, and Colonial America. Nevertheless, the term guild or craft guild refers to a particular type of artisanal association, which had its place in the corporate societies of Europe from the late Middle Ages to the nineteenth century. Despite enormous variations from city to city, region to region, and one historical period to another, the concept of the guild refers to a combination of several characteristics. First, a major organizational principle was occupation. Usually, although not necessarily, guilds organized artisans of the same occupation or of related/similar occupational groups, and occupation formed the major line of differentiation separating one guild from another. Changes in the division of labor and in occupational structures are therefore the major dynamic forces in the development of the guild system. Second, guilds were strongly concerned with economic matters in their respective sector of the economy. Market regulation – both in respect to commodity markets and labor markets – was an essential part of their economic activities. Third, guilds were primarily organizations of master craftsmen. Occasionally they also included apprentices and journeymen in minor positions; on other occasions, they definitely excluded these groups, thus providing the impetus for journeymen to find their own clandestine or legal associations. Fourth, guilds were formally constituted and officially recognized bodies. Statutes or privileges granted by municipal or state authorities made them a solid part of the corporative structures of society. In this context, guilds also performed political functions, casually participating in the political system, occasionally even dominating urban politics. Lastly, guilds were not only economic and political bodies, but also multifunctional institutions engaged in religious, cultural, and social activities.

The first guilds – in the sense of this definition – were established in France, England, Germany, and Italy in the twelfth century. In the thirteenth and fourteenth centuries, guilds existed almost everywhere in urban Europe with a wide variety of titles and designations. Latin sources use terms such as *officium*, *ministerium*, *magisterium*, *artificium*, *collegium*, and many others. The French language speaks of *métiers*, *corps des métiers*, or *corporations*; in English they are called guilds, crafts, or mysteries; in German *Zunft*, *Zeche*, *Innung*, or *Amt*; in Italian *arti*, *gremi*, and so on.

Guilds in Corporate Society

Despite these obviously medieval roots, European guilds became a mass phenomenon and a nearly universal institution in the Early Modern Era. In the Netherlands and France, Spain and the various Italian states, German-speaking Central Europe, and the Nordic countries, most guilds were founded in the sixteenth, seventeenth, and eighteenth centuries. Even in England with its highly developed market economy, many guilds were reestablished in the Restoration, and in cities like Bristol and Bath, there were even new guilds being founded as late as the mid-eighteenth century. A guild system also developed in the Ottoman Empire, particularly in the Balkans, the Near East, and Northern Africa. In the Russian Empire, on the other hand, guilds were unknown. In Colonial America during the early eighteenth century, many artisans took an interest in setting up craft guilds. Even though some associations were actually founded (such as the Carpenter's Company of the City and County of Philadelphia in 1724), no general guild system came into being.

Even when guilds were at the pinnacle of their importance in Europe, not all artisans were incorporated. In Western Europe and particularly in France and England, guilds were limited to cities, and did not even exist in all cities. In many Central European states – for instance, Austria – guilds transcended municipal boundaries and became regional or nationwide institutions organizing urban artisans as well as craftsmen from villages and the countryside. In those places where guilds did exist, there were few instances in which all artisans belonged to them. A large proportion of artisanal labor always took place outside of the guild system.

Mercantilist theorists and political leaders of the seventeenth and eighteenth centuries regarded guilds as instruments of unified state regulation of trades, labor, and taxes. During this period, many European states indeed tried to make guilds universal and to establish the guild system as a framework for all economic activities; one such example is the effort of French Prime Minister Colbert in his trade laws of 1673.

The End of the Guild System

A hundred years later, the opinion of guilds held by political and intellectual elites had changed completely. During the second half of the eighteenth century, an antagonistic discourse emerged. Mainstream economic and political thought – expressed in the fields of political economy, physiocracy, or in Enlightenment thought in general – came to regard guilds as obsolete relics of the past that sought to retard or prevent economic development. Proponents of this approach called for complete freedom of trades and the abolition of guilds. Conclusions diametrically opposed to these were drawn by conservative thinkers who saw guilds as the embodiment of a corporative ideal and as a means of combating the assumed decay of authority and order.

When the leading physiocrat and Enlightenment thinker Turgot served briefly (1774–76) as French prime minister, he issued a decree in 1776 completely abolishing all guild privileges as well as expressly forbidding "all masters, journeymen, workers, and apprentices (…) to form any association or assembly among themselves (…)" (Sewell, 1980: p. 73).

Despite the fact these measures were repealed only a few months after Turgot's fall from power, they nevertheless initiated the process of the elimination of guilds from Europe over the course of the next 100 years. Revolutionary France took a radical step as early as 1791 and banned guilds along with all other labor organizations. England's Combination Acts of 1799/1800 also mandated the 'prohibition of all combinations' – those of masters as well as of journeymen (Chase, 2000: p. 84). Most Central European states oscillated between anti-guild and proguild principles. They indeed forbade the organization of artisanal workers, but permitted the guilds – as organizations of masters – to remain in existence. It was not until the 1860s that the guilds were dissolved once and for all in the German states and in the Habsburg Monarchy. This process reflected the guilds' loss of their social function. In most countries, dissolving the guilds met no opposition, but it was precisely in Central Europe that guilds remained alive as the object of the projections engendered by a corporative social ideal and conservative nostalgia.

Guild Traditions in Petit Bourgeois and Labor Movements

The end of the guild system did not also mean the end of artisanal organizations. These developed over the course of the nineteenth century in two separate directions. On one hand, there was the organizational continuity of master artisans, independent craftsmen, and employers. This line of tradition was significant above all in Central Europe. In the German and the Habsburg Empires, in Denmark, and in some other countries, cooperative organizations in the crafts and trades continued to exist even after the dissolution of the guilds. From the 1880s, these organizations were granted wide-ranging authority in their respective fields, such as control over the training of apprentices. Politically, these trade associations were closely associated with the 'middle-class movements,' the political movements of the *petits bourgeois*. They demanded the restoration of guilds and developed corporative ideals in the framework of conservative and right-wing politics (cf Haupt, 1996).

The tradition of guild crafts and trades, however, also played an important role in the emerging labor movement. Although journeymen's associations had been banned in many European countries at around 1800, confraternities, *compagnonnages*, houses of call, and similar institutions continued to exist on an informal or illegal basis. Although there was no direct institutional continuity between guilds and trade unions, there was nevertheless a close connection on the conceptual, experiential, and personnel levels. Artisanal workmen who came out of guild traditions were used to organizing in such associations, which they considered their political right. They were likewise accustomed to settling labor disputes collectively, be that in the form of negotiations or job actions. Furthermore, they also carried on the tradition accentuating and defending their social status, which was based upon the 'property of skill.' All these traditions were important incentives for the founding of the first trade unions in the first half of the nineteenth century.

In a broad sense, artisans were also the driving force behind the early political labor movement. Of course, the concept of class contradicted the tradition of craft consciousness, since it stressed the common experiences of all workingmen, skilled or unskilled, in whichever craft or trade they engaged. Nevertheless, there is almost universal agreement "that skilled artisans, not workers in the new factory industries, dominated labor movements during the first decades of industrialization. Whether in France, England, Germany, or the US, whether in strikes, political movements, or incidents of collective violence, one finds over and over the same familiar trades: carpenters, tailors, bakers, cabinetmakers, shoemakers, stonemasons, printers, locksmiths, joiners, and the like. The nineteenth-century labor movement was born in the craft workshop, not in the dark, satanic mill" (Sewell, 1980: p. 1).

Revisionism in Guild and Artisan Historiography

The negative assessment of guilds in eighteenth- and nineteenth-century thought also characterized historiography. Until recently, most historians had assumed that guilds were technologically regressive, that they restricted economic growth and strait-jacketed the development of free market capitalism.

All of these assumptions have been subjected to critique since around 1980. A growing number of historians is now engaged in a 'revisionist version of guild history' (cf Epstein et al., 1998; Ehmer, 1998). With respect to early modern Europe, artisans and guilds have become reintegrated into the mainstream of the development toward capitalism. The Dutch case shows most clearly what can be seen in many other European regions as well: 'guilds were part and parcel of commercial capitalism,' showing extensive growth particularly in the 'Golden Age' (Lucassen, 1995). The increasing dependency of Europeans on markets and the growing variety of available goods and of artisans who made them are now seen as evidence of a "dynamic, flexible, and creative craft economy" (Farr, 1997: p. 25). The guilds' emphasis on skill, their system of formalized training, and the technological transfer through tramping artisans, are now said to explain, 'the undisputed technological leadership of guild-based production', particularly in comparison to the rural putting-out system (proto-industry) and early centralized factories (Epstein, 1998: p. 705).

Furthermore, guilds are no longer regarded as stable institutions of equals, but as highly stratified and dynamic fields of social relations. Merchant capitalists used some guilds to control and discipline economically dependent masters and journeymen, whereas other guilds were instruments of resistance to merchant capital. There are also new perspectives on artisanal cultures, conceptualizing them as historically variable and adaptable sets of practices. In this new light, customs that were regarded as 'ancient' by the artisans themselves as well as by the historians who came after them are now often being shown to have a rather brief history. For instance, French *compagnonnages*, journeymen's associations with highly elaborate rituals and an aura of mystery, experienced their 'golden age' from the mid-eighteenth century to the 1830s or 1840s – the very period of redefinition of the position of artisans and guilds in society (cf Sonenscher, 1987: pp. 31–63).

Another area in which revision is taking place is the role of the artisans in the Industrial Revolution. In eighteenth- and nineteenth-century Britain, small-scale and labor-intensive production, skill and 'hand technology' drawn from a huge reservoir of urban and rural artisans played a key role, not as

a mere remnant of the past, but as a central and dynamic component of industrial capitalism (cf Berg, 1985). Generally, artisanal small-scale production displayed remarkable persistence in industrializing societies, adapting to the needs of industry, and benefiting from the growing demand of consumer society. The generally successful process of adaptation was not harmonious and free of conflict. Some artisanal branches survived, some new ones were born, but others – including all textile production and most metal manufacturing – declined and vanished. Artisans in these trades experienced the devaluation of their skills. The same happened to the journeymen of the metropolitan garment industries, which left the artisans' workshops and became reorganized as an urban domestic industry based on the cheap labor of women and children instead of that of skilled workmen.

The role of women in the world of the artisans is a major point of recent discussions (Hafter, 1995; Hanawalt, 1986). It is generally agreed that women in most human societies regularly performed artisanal labor, but rather seldom became artisans in the sense of professional, organized, and honorable workers. In European history, the concepts of artisan and, to an even greater extent, guild were male concepts. Artisans who practiced crafts and trades in European cities during the late Middle Ages produced commodities that had previously been produced in households by women as well as by men. The difference was that the professional artisans then produced for the market and their labor became regulated by a set of formal and informal rules. Even if 'the early guild ordinances (…) did not regard skilled guild labor as a male preserve,' in the long run the switch from household production to market production, from unregulated artisanal labor to a 'craft,' excluded women (Wiesner, 1989).

Recent research clearly shows that women participated in artisanal labor in many respects, as masters' wives and daughters, as domestic servants in artisans' households, as widows, and, last but not least, as autonomous independent producers. Nevertheless, in all these roles they were not officially recognized as skilled workers. This shows that the very concept of skill, which is central to the conception of the artisan, is highly ambiguous. On one hand, skill indeed requires a certain body of knowledge, experience, and training; on the other hand, skill is a historically variable social construct. Not all labor activities that require some expertise are regarded as skilled work. In European history, skill was defined by male artisans and guildsmen not only with respect to actual work practices, but also as property, status, and a means of social distinction.

Artists, Competition and Markets

Abstract

Income distribution in art occupations is highly skewed. Abilities and talent seem to be better candidates than initial training to explain skewness. Yet quality differences among artists and works play a puzzling role: They can be detected only through comparisons, but the standards of comparative evaluation must remain indeterminate enough to allow for substantial differentiation and competition through originality and innovation. Careers are patterned by comparative tournaments: Even tiny differences at the outset suffice to trigger a mechanism of cumulative advantage, with attention and reward being concentrated on those favorably compared, out of proportion to the underlying distributional gap of abilities and skills. Assortative matchings lower the cost of creative invention. Thus initially boundless interindividual competition, with its distinctive excess supply mark, gradually results in stratification by reputation and status.

Income distribution in art occupations generally follows the Pareto curve: One-tenth of professionals in the given field earn half of all annually distributed income; one-fifth earn 80%. In art there are more individuals earning nothing – or less than nothing after art-related expenses – than in any other higher occupation. At the other extreme we have the elongated tip of the distribution, signaling the presence of artists with astronomically high incomes – a level that brings to mind lottery payoff matrices. To what mechanisms of the artistic labor market should this discrepancy and the resulting extreme inequalities be attributed? Earnings distribution is structured entirely differently from the skills and qualifications distribution associated with wage equations. Whereas the distribution of human capital factors of the sort included in wage equations typically forms a bell curve wherein individuals of the given population are fairly symmetrically distributed around mean values and the majority of individuals are at the center of the distribution, in creative jobs we have an extremely asymmetrical curve. This is where market organization of artistic production and consumption come under suspicion. The critical view of inequality-generating mechanisms suggests the Paretian distribution of rewards demonstrates the true pathologies of a competition-driven market organization. The primary aim of this article is to explain such a skewness and to refer careers in creative undertakings to mechanisms of quality detection and evaluation that are both indeterminate enough to let innovation lead the game and efficient enough to translate uncertain occupational prospects into wide gaps in reputation, status, and rewards.

Job Stratification

Acccording to the theory of job stratification (Stinchcombe, 1986; Jacobs, 1981; Baron and Kreps, 1999), each occupation can be assigned certain characteristics and capacity requirements whose social and economic values are assessed according to their degree of scarcity and the nature of the collaboration between those working together. The degree of scarcity reflects the vertical ranking of abilities, skills, and performance: An extraordinary talent will be admired and, where a market value exists, exploited at considerable profit, provided that it is sought after by a sufficient number of people willing to pay for it. Moreover, a talented worker may make an unusually high contribution to the success of his organization, more than proportionate to the differential between his qualities and those of his teammates. It is in these professions that competition to attract and reward individuals deemed exceptionally talented is fiercest and it is here that earnings concentration creates winner-take-all or winner-take-the-most situations (Frank and Cook, 1995). In such professions, the probability of obtaining an exceptionally fine result is low and most performances produce average results. The cost for the company of hiring an average professional is low compared to the profits it will reap if it finds someone exceptional, and this leads to an employment policy or contract relationship that brings in a great number of different individuals, the aim being to find the 'real gem.'

Let's call these jobs 'star jobs,' following Baron and Kreps' reworking of the stratification model of Stinchcombe, with its distinction between 'star jobs,' 'guardian jobs,' and 'foot-soldier jobs.' To look where to find 'star jobs,' one may think of scientific research, sports, the entertainment industry (cinema, radio and television, concerts, shows, and performances for a wide audience), and the arts. Yet not all of the artistic occupations entail this 'star job' profile. The creative artist (novelist, painter, composer, and solo performer) obviously holds a 'star job,' as characterized above.

Artistic jobs like that of teacher or orchestra musician primarily falls into a second category, that of 'guardian jobs': In these, even spectacularly excellent individual contributions cannot bring the organization or team any additional reputation or profit. In these jobs, the skills required for performing the activity are an 'additive' production factor and they are more homogeneously distributed among the individuals concerned. Lastly, extra-artistic activities are usually the equivalent

This article draws on models and analyses expounded in my forthcoming book *The Economics of Creativity: Art and Achievement under Uncertainty*, Cambridge: Harvard University Press, 2014.

of 'foot-soldier jobs': Within them, variation in individual performance has limited impact and the range of individual differences is of very limited value. Here the success of the organization depends on the aggregation of all individual performances. Employees are hired on the basis of a simple wage negotiation: Anyone who accepts the proposed wage gets hired.

Star Jobs and Paretian Distribution of Earnings

Clearly, star jobs (i.e., primary creative activities) are those that earn their successful incumbents the highest rewards (monetary and nonmonetary, like esteem and social recognition) and those for which cultural enterprises such as publishers, gallery owners, and recording and film companies are very clearly looking for the rare gem.

In these jobs, high value is laid on expertise and talent, and perceived differences in quality are of decisive importance in orienting the buyer's preferences. Thus given that demand is highly sensitive to differences in quality, at a given price for a good or service, a buyer's utility will be greater if she chooses a professional who is considered more talented than another. This seems quite obvious when objective quality superiority is at stake. A surgeon with a 10% greater ability to save lives than others will be in greater demand. His fees and aggregate earnings will exceed those of his colleagues by much more than 10%. Thus, if the question is why differences in reward can be extremely disproportionate to differences in ability, the first answer lies in the mechanism that concentrates earnings on the basis of perceived quality differences and nonlinear increase in expected utility from higher quality (Rosen, 1981; Goode, 1979).

The situation in the arts looks somewhat different at first sight, as it leans toward the subjective side. In contrast to the surgeon, artistic talent and art commodity quality differentials point to subjective utility. Yet a quality difference that yields greater subjective utility is an inherent feature of the service demanded by the audience: It is precisely what the consumer is looking for. Without the assumption that quality differences play a fundamental role in orienting consumer preferences, we could not understand why there is competition among artists. And this assumption was precisely ruled out by the Marxian attack against the market organization of production as functionally and economically separated from consumption. For, as in the case of the superior surgeon who saves more lives than another (but with much less dramatic consequences), an artist deemed superior is much more desirable than an artist of inferior quality, and this should hold without consumers being subjected to any kind of external influence. Two concerts, exhibitions or films of moderate quality will not give me as much satisfaction as one high-quality concert, exhibition or film. The quality perceived as superior is powerful enough to trigger demand concentration and therefore celebrity and wealth for those artists reputed to have the greatest talent.

Providers deemed to have superior talent have a larger market share that may extend immensely due to joint consumption technology: Digitization, trading networks, and duplication of commodities enable artists to serve instantly very large markets. Audiences are potentially enormous relative to the scale most of us operate on. And even if a provider is unable to clone himself and the commodities or services he supplies cannot be reproduced (surgery, consultancy, painting, and concert performances), his career can develop on a worldwide scale like that of a small number of famous practitioners in great demand in each trade.

How to Cope with Quality Uncertainty? Talent, Tournaments, and Excess Supply

Up to this point, we stand on the demand side. The argument relies on two key assumptions: (1) quality differences in production and performance can be perceived; (2) quality differences should be perceived without bias, otherwise quality evaluation is subject to manipulation and as it is well known, bad quality eventually crowds out the good one.

How to detect and rate quality differences? It would be easy to evaluate artists and their work and perceive qualitative differences if everything could be assessed in absolute terms, on the basis of a univocal scale and a stable set of perfectly unambiguous criteria. The selection process in the course of initial artistic training would perfectly filter the many candidates through some simple tests and contests. Things take another course once ability is viewed as a multidimensional and multifactorial component. Indeed, the fundamental properties of a creative activity are unlimited differentiation of its products (Caves, 2000) and originality-driven competition. Therefore, in stark contrast to a timed athletic performance or problem resolution, esthetic originality and artistic value can only be measured in relative terms. And reasoning in terms of success factors would become spurious: It is, of course, the *combination* of various types of qualities and skills that counts, but there is no detectable ideal formula for an optimal combination or optimal proportions of those qualities and skills. We suspect that the skewed distribution of those qualities and their indecipherable combinations may create sharp inequalities in chances of success, but it is impossible to estimate that distribution a priori. This is why people engage in relative comparison.

Competition in a given market determines the value of artists' accomplishments. It does so through the intensity of immediate preferential demand, and through a flow in demand which is linked to the durability of the artwork and to the interdependencies between the artworks that are successively produced over the course of an artist's career (since the success of one artwork can trigger enthusiasm for the artist's previous works, and bring heightened attention to those that follow). The quality of each artistic good supplied is uncertain. It is impossible to directly assess the abilities of artists through skills measurements and standardized tests, no less than it is to assess the value of artworks using an unequivocal scale of measurement and a stable set of unambiguous criteria, as the fundamental property of artistic activity is driven by competition for originality. Thus, in contrast to a timed sports performance or the solving of a problem, esthetic originality and artistic value can only be measured in relative terms. The rankings, reward schemes, and career advancement profiles must take the form of tournaments (competitive tournaments in music, recruitment through auditions, awarding of prizes,

hit parade rankings, critics' evaluations and scorings, etc.) in which evaluations are based on incessant comparison. Artists work to differentiate themselves from one another on multiple levels so as to make their mark in the competition. However, critics, art world professionals, market intermediaries (producers, employers, organizers, and agents), and consumers never cease their rankings. Initially dispersed, evaluations gradually align, due to affiliation processes (Van Rees, 1987). The cultural knowledge required to appreciate and assess artworks can be defined as the sum of significant comparisons an individual is capable of making, explicitly or implicitly, for the purpose of attributing meaning and value to an artwork. Thus, artworks initially juxtaposed through the law of originality become hierarchically ordered by audiences and art world professionals, through a series of competitive and comparative tests, according to their preferences and investments. What is called "talent" can be defined as the quality gradient attributed to the individual artist through these relative comparisons. The difficulty in defining talent rests in that it is not an arbitrary value, but rather a purely differential quality (Menger, 2014).

These characteristics are reflected in the twofold, operational strategy of cultural entrepreneurs: the exploitation of uncertainty, which is a condition for entrepreneurial profit, and the reduction of uncertainty. Very little is known about the ingredients for success. Uncertainty about the market potential of each artwork and innovation therefore pushes each firm to hedge its bets across a broad range of artists; this drives cultural industry entrepreneurs as a whole to feed, through a composition effect, a structural excess supply characterized by seasonal peaks and short term fluctuations (Hirsch, 1972).

Yet, as soon as cultural entrepreneurs manage to identify an artist with 'high potential,' they set about overexposing him and activating the mechanisms of contagious imitation in the general public. They do this by exploiting the self-reinforcing dynamic that transforms an artist's success into both an effect and a cause of the quality attributed to him by consumers. They may then seek to 'develop' the artist who has enjoyed his first successes, just as is done in research and development with scientific inventions or technical innovations. Thus, after having taken advantage of the uncertainty about who will emerge as winners by exploiting competition through differentiation, cultural entrepreneurs endeavor to reduce uncertainty about a promising artist's chances of future success by seeking to transform his instant value into a lasting one – a sure asset in which it is possible to invest.

Should the problem of artistic overproduction simply be regarded as the modern phenomenon of the industrialization of culture? In fact, nearly every sociologist, economist, and historian who has ever studied artistic labor markets has underscored the excess supply of artists (Ehrlich, 1985; Graña, 1964; Lenman, 1989; Montias, 1996; White and White, 1965). If overproduction is as frequently invoked as a disease caused by the industrialization of culture, it is because cultural industries are constantly organizing and reorganizing themselves so as to turn overproduction into an advanced technique for managing uncertainty and into a mechanism for increasing profitability. The wide range of influences exerted by cultural entrepreneurs over consumer choice and over the evaluation of competing artists is illustrated here with the greatest clarity.

In effect, the entire architecture of the cultural industries (music, book, cinema, and audiovisual production) has been built on organized relations between the production, distribution, promotion, and consumption of artistic goods and services – thereby generating competition through tournaments (hit parades) to identify profitable talents. The basic economic principles at work here are well known (Curien and Moreau, 2006; Benhamou, 2008; Connolly and Krueger, 2006). The form of competition in this sector is that of oligopolistic concentration. In the music industry, for example, a few big firms realize three-quarters of the world-wide turnover for the sector, and a nebula of so-called independent producers maintain relations of 'coopetition' with these major labels. Concentration is explained by the cost structure: In the music and book industries, the cost of producing a good (the acquisition and payment of the raw material – creative labor) and the cost of material production are proportionately low and variable, whereas the costs of distribution and promotion are high and fixed (accounting for three-quarters of total costs). Industrial concentration is, consequently, motivated by economies of scale linked to the distribution and commercial exploitation of a raw material – artists' creativity – that can be obtained and controlled at low cost, even though its market value is difficult to predict.

The structure of competition reflects this way of proceeding. Large firms find it more profitable to let independent producers act as adventurous explorers – as risk-takers and fine connoisseurs of market niches and emerging trends – and to engage in cooperative competition with them, via the distribution of their products and financial participation in their capital. This is the classic figure of 'oligopoly with a competitive fringe.' Small firms devote most of their resources to scouting talents and to financing their own productions. The major firms, meanwhile, extract rent via the distribution of independent productions, buy up the contracts of independent producers with successful artists, develop the most promising careers, ally themselves with stars, and work on triggering and reinforcing the dynamics of success amplification through investments in advertising and promotion. The picture should, however, not be painted in such binary terms: The major firms themselves are in reality entire galaxies in which labels behave like autonomous centers of production and profit while also acting as talent scouts. Nonetheless, the distinction according to size continues to hold; it imparts its characteristics on the demographics of firm population, resulting in a high mortality rate for small firms, growth for more skillful or fortunate ones, buyouts, mergers, and firm concentration. Furthermore, the pattern of concentration has changed: In continuity with past practice, vast multimedia groups have been formed that produce and distribute their own products along with those of other producers, and that control publishing companies (with copyrights protected for ever longer periods of time). However, these groups currently have much greater control than before over radio and television stations and over commercial operation networks (e.g., retail sales, on-line sales, and payable downloads), enabling them to directly activate the levers of success amplification.

Under conditions of flexible specialization, the number of independent producers grows, even as the rate of sector concentration increases. What is, in fact, also on the rise is the

density of independent producers' interdependencies with both other firms and dominant companies (Hesmondhalgh, 2002). Thus, the 'openness' of the system of competitive production explains why, despite the fact that the rate of oligopolistic concentration in the recording industry has increased since the early 1970s, rates of innovation and diversity in musical production (as calculated on the basis of hit parades) either remained stable or increased throughout the 1980s (depending on the indicator chosen (Peterson and Berger, 1975; Lopes, 1992)).

Assortative Matchings

In the models I have discussed thus far, spectacular inequalities in success primarily concern the specific situation in which artists or professionals with valued expertise are competing to attract demand – each acting individually, through direct interaction with the market, and without any apparent partners. However, in order to work and to produce and diffuse their products, professionals usually join a permanent or temporary organization (e.g., orchestra, theater company, film production crew, etc.); alternatively, they enter into a contract with an organization that acts as an intermediary (e.g., publishing house, recording company, or art gallery) in order to create material reproductions of a given good, place an artwork into circulation, and gain access to the market. It is here that another trigger of inequality comes into play: assortative matching.

Assortative matching characterizes the multiplicative nature of the production function in artistic labor. Like a scientist in Merton's cumulative advantage model (Merton, 1968), an artist benefits from associating with professionals reputed to be of equal or superior quality in their respective careers. Indeed, in order for an artist to secure the best chances of developing his talent, it is important for him to associate with professionals of comparable value working in the other professions involved in the production and circulation of artworks. For example, a reputed director will seek to enlist top professionals in the key positions of a film production, and the head of a publishing house will entrust his most seasoned literary director with the task of managing labor relations with the company's most talented and promising writers or with the latter's agents (Thompson, 2010). Furthermore, in the very early stages of artistic and scientific careers, formal learning trajectories followed by on-the-job learning (and even by apprenticeship, a persistent form of artisanal organization in certain artistic and technical-artistic trades) are heavily determined by an individual's association with experienced partners. These are the people who provide an artist on the path toward professionalization with better opportunities for developing skills in demanding projects, through contact with fellow artists who have themselves been selected based on their potential.

Art worlds combine labile organizational architectures (e.g., network, project, and vertical disintegration) with teams structured through the association of professionals of equivalent quality or reputation – that is, through assortative matching. Labor markets for the most highly qualified jobs are, in this way, hierarchically ordered by professional pairings. A successful career dynamic constitutes a movement of upward mobility in a world stratified by networks of acquaintances and recurring collaborations. In my above presentation of the existing analyses of job stratification by functional importance, I highlighted that, in the practice of an artistic profession, talent is a complementary rather than additive factor of production. Assembling talents of approximately equal level – each in their respective function (interpretation, organizational mediation, editing, fundraising, etc.) – has a multiplicative effect on a given project's chances for success and on the project collaborators' chances of accumulating reputation (Rosen, 1983; Kremer, 1993). The interdependence of performances renders the benefits of this relationship complementary: A publisher who attracts talented authors will increase his own chances of expanding his experience and renown in the editorial field, just as a talented author will benefit from collaborating with a publisher reputed for his professional qualities.

Faulkner (1983), in his study of Hollywood cinema, demonstrated the power of assortative matching in the cultural industry. Accominotti (2008) has since shown that the mobility of painters in the gallery networks he studied follows a similar mechanism. Numerous studies dedicated to scientific careers, networks of collaboration and copublication among researchers, and upward mobility in the American academic labor market, have likewise revealed how: (1) Stratification of the professor–researcher population by reputation level (in terms of productivity, visibility, and readership) regulates collaborative pairings; and (2) The recruitment and career mobility market is governed by the rule whereby the candidate's relative value must be matched to the institution's position in the hierarchy of excellence.

We can easily connect the assortative matching argument to the dynamic analysis of careers based on the mechanisms of competitive tournament and cumulative advantage. In the course of artists' early formative experiences, capacities manifest themselves differently and unequally according to each individual. What still remains undetermined, however, is the nature of the differences in talent that exist between the creators who, over the relatively long term, will achieve success – either lastingly or not – and those who will fare less well. Expressed in terms of probabilities of success, the advantage gained from demonstrating a potential talent early in one's career may indeed be weak; yet any (great or small) difference perceived in each test of competitive comparison suffices to polarize the investments and wagers of system actors (i.e., artists themselves, trainers, professionals, patrons, entrepreneurs, critics, and consumers). The learning content of different work situations relies on the same mechanism: There exists an optimal profile for expanding one's skills, which is a function of the number and variety of work experiences and of the quality of the collaborative networks mobilized by the artist as he moves from one project to the next.

The relative comparison of artworks and artistic performances conducted in competitive tests, together with the lasting indeterminacy of the course of creative activity, imbue artistic labor with a continual tension. It is on this basis that analyses of the gaps in reputation and success put forth the causal role of networks of interdependence and cooperation in artistic labor. In order to create and diffuse their works, creators and artists enter into contractual relations with

organizations, such as artist agencies, publishing houses, recording companies, painting galleries, production companies, etc.

Selective tests, as well as information on the value of an artist's commitment to creative labor provided step by step to himself, his peers, his colleagues, and his supporters, allow us to understand the career dynamics of artists foremost as a learning trajectory within a segmented system of activity. Whether we focus on the professionals who sponsor the artist's debut, on his partners, or on the various other categories of art world actors with whom he establishes work relationships, it is through the development of collaborative networks that an artist organizes his activities. This is especially so given that he must mobilize diversified resources in order to develop his work capabilities.

Two remarkable consequences of assortative matching must be highlighted. First, the multiple and incessant evaluative judgments, on the basis of which reputation hierarchies are constructed, act as structuring forces that segment a professional milieu whose activities do not fit in a stable organizational mold. Second, gaps in talent that are initially small, or at the very least of uncertain importance with regard to future success, are rapidly increased by the game of assortative matching – and this, due to the multiplicative effect this game has on the expression of the individual qualities of collaborators, and to the authority it bestows on those who co-opt each other for their creative projects.

We are now in a better position to understand how a hierarchy develops. A hierarchy is founded on reputation, which has the functional property of an efficient vector of information and investment in a universe of sharply differentiated activities and goods. Neither art world professionals nor consumers can estimate through direct experience the value of every artist and artwork; nor can they continuously reestimate an artist's value in the shifting context of incessantly renewed competition. As Stinchcombe (1968) explains, the vocabulary of talent, genius, brilliance, and creativity is a common means of attributing extraordinary qualities to individuals in sectors of activity wherein success is highly uncertain (e.g., the arts, research, and advertising). The primary semantic function of these terms is to draw a sharp distinction between these extraordinary qualities and all the other typically measurable qualities of an individual. Furthermore, these terms are essentially assigned a posteriori, as a means of domesticating and categorizing that which is unmeasurable – that which cannot be predicted but only 'retrodicted.' This vocabulary acts to convert an uncertainty dispelled a posteriori (in light of experience) into an expectation of success. Insofar, the attribution of talent acts as a mechanism for reducing social complexity.

The increase in artist reputation reveals the existence of a mechanism of cumulative advantage. The artistic career presents itself to a young professional as a succession of comparative tests in which each performance is judged individually. For an artist who has completed a series of such tests, reputation constitutes a form of capital that can be managed in various ways to protect him from the variability of instantaneous evaluations and to more rapidly increase the benefits derived from his fame. Ascribing talent leads to granting a more stable value to the favored artist and his works; insofar as it is equated with the substantial qualities evoked by the artist's name, this value becomes incorporated into the artist's identity and lowers the costs of attracting critical attention (Van Rees and Vermunt, 1996). Rather than defending only artworks, publishers and art dealers support artists themselves. They thus contribute to building artists' careers, and urge consumers to focus their interest and cultural investments on these specifically (White, 1993).

An artist's reputation rating allows for his integration into a system of stratified relations: It is profitable for an artist to be associated with other artists and professionals of at least equivalent standing. The game of relations of exchange and collaboration defines a hierarchy of artist status. In a competitive system of this type, an artist's position in the hierarchy is associated with the reputation he has accumulated. This position becomes a 'status': a hierarchical indicator of quality utilized in a system of relations and exchanges that is more stable than the sum of information contained in the value attributed to an individual's different accomplishments (Podolny, 2005).

Thus, reputation reduces uncertainty, and status reduces uncertainty about the current informative value of reputational signals linked to past 'enactments.' The complete trajectory of reputation accumulation no longer matters when we assume that the value ascribed to an artist – his status, as Podolny puts it – sums up and guarantees all of the information produced and exchanged in the art world concerning that artist's relative quality.

Reputation, of course, can always be contested so long as it continues to be subjected to tests of interindividual competition. Nonetheless, through the mechanisms of self-reinforcement and assortative matching, reputation offers deeply unequal opportunities for the actualization of creative talent, no matter how small and indeterminate this talent's initial distinctive value may be.

Careers and Markets

If we now consider careers and markets together, we see that there are two causes for the excess supply of artistic goods and candidates for an artistic career. First, the number of artists and the variety of artistic production increase faster than demand, because overproduction is a rational response of firms to an uncertain environment. Second, the organization of artistic production on a project-by-project basis, which helps minimize the fixed costs incurred by the schema of rational overproduction, relies heavily on temporary contractual relations with the diverse categories of professionals involved in key operations (from the creation to the distribution of artistic goods). One characteristic of this mode of organization is that it generates an excess supply of labor, available for any project that might solicit it.

As careers of artists unfold outside of the stable organizational structure provided by a firm, they generally follow a trajectory of projects realized through a string of contractual transactions, and for which there exist none of the guarantees associated with ordinary wage labor. As a result, making a career implies getting through elimination tournament stages and that getting through those stages means beating chance.

The forward progress of a career works to reveal underlying the individual's qualities and strengths (those that enabled him or her to get through the stages), qualities and strengths that are unequally distributed among individuals. An individual who succeeds in developing her career in the project-by-project context can enjoy the benefits of a well-established reputation, padding her relational network with contacts that will convey information and work offers through which to increase her skills. This dynamic is particularly influential in occupations where on-the-job learning plays an important role and where the reputation signal is a highly functional means of passing on information in professional network exchanges when it comes to organizing projects.

The importance of 'on-the-job' learning is explained by the heavy exposure of an individual's work to the uncertainty of an extremely turbulent environment; that is, organization on a project basis and the variable degree of control that the individual has over the result of team work. A successful career can be likened to a gradual increase in artist's control over the relatively variable dimensions of her activity and over relations with her environment, in a world where stratification by reputation – unlike in the sciences – is disconnected from stable work organization. It is the very system of artistic labor that creates conditions allowing chance to intervene. Art careers are constructed from one project to the next, and not all projects are equally likely to be successful. Moreover, the individual's work is usually immersed in a collective undertaking whose chances of success are imperfectly correlated with the quality of each team member. The skill or talent of an actress evaluated in terms of personal performance do not fundamentally differ, of course, by whether the film she plays in is a success or failure, but her visibility and the likelihood that she will be involved in more or less promising projects later on depend in large part on the film's success. Organizing work on a project basis introduces strong variability into professional activity and multiplies possible bifurcation points; for example, being called in at a moment's notice to replace the star opera singer, who has caught cold; discovering just the right information on a future project or employment opportunity; landing a role in which, against all expectations, one can reveal one's aptitudes without having ever been cast in that job category before. Project complexity increases the role of chance and in some cases the sequence in which good or bad luck strikes. Moreover, there are few occupations whose practitioners make such frequent recourse to superstitious practices and rituals, the counterpart to that other essential behavior mechanism characteristic of the art world: excessive self-valuing.

In this context, artists' careers can be analyzed as a stochastic process (MacDonald, 1988; Fox and Kochanowski, 2007). Young artists are uncertain about the quality of their work, and their professional engagements constitute a series of evaluative tests (exhibitions, publications, performances, or concerts). If initial evaluations by peers, critics, and members of their reference group are favorable, they will choose to pursue the profession. Artists who achieve lesser or very little success in this first career phase are exposed to a mechanism of cumulative disadvantage. Whether artists remain in the profession with hopes of overcoming the negative effects of a mediocre debut depends on the resources available to them for managing career risks (e.g., multiple jobholding, unemployment benefits, entrepreneurial initiatives, public subsidies, and diversification of activities in order to acquire visibility), as well as on the value artists attribute to the nonmonetary rewards they obtain from their activity, as compared with alternative activities that may offer greater chances for success.

A cohort of artists who have simultaneously entered the market therefore includes a majority of individuals who earn low income and obtain only modest success or rapidly encounter failure, and a minority of professionals who emerge successfully from the competition in the first career phase. Income inequalities reflect the composition effects of the artistic population, the growth of which is driven by two mechanisms. First, the number of entrants hoping to make a career in the arts increases faster than the proportion of those who are relegated and eliminated by the competition. Second, artists in a given cohort who choose to pursue their careers are made to compete with artists from prior cohorts; their position in the competition does not depend on their employment status, as in an organization with seniority and hierarchical positions, but instead on the estimated value of what they produce and on their chances of maintaining their position or raising their status. Thus, careers distribute artistic professionals according to a reputation hierarchy which is based on their past accomplishments and expectations to deliver work and performance of the same quality.

When viewed in instantaneous cross-section, the hierarchy of artist reputations appears to express substantial differences in quality, as revealed by a series of comparisons and competitions. However, as Rosenbaum (1989) has underlined, comparative rankings do not merely reveal unequally distributed qualities, and then select individuals on that basis. These competitions cause divergences in contenders' career paths, despite the fact that their abilities may have been similar. The concentration of earnings and reputations on a very small number of individuals could therefore correspond to gaps in success that are far greater than the gaps in abilities known as talents. The signal emitted by winning a competition helps trigger the process of reputation accumulation.

We readily see the connection between the assortative matching argument and the analysis holding that careers in art advance by way of tournament competition and cumulative advantage. In the course of their early, formative experiences, would-be artists manifest capacities in ways and degrees that vary by individual. The nature of what kind of difference in talent exists between creators who will succeed (more or less lastingly) and others who will not come out as well remains undetermined. Expressed in terms of probability of succeeding, the benefit that hoped-for talent provides early in an artist's career may be weak, but it will be enough to create a small, or not-so-small and in any case perceptible difference with each competitive comparison test, and this in turn will polarize the investments and 'wagers' of system actors (artists themselves, trainers, professionals, patrons, entrepreneurs, critics, and consumers). The intrinsic learning content of work is of a similar origin. There is an optimal profile for increasing one's skills: It is a function of the number and variety of work experiences an artist has and the quality of the collaboration networks she can mobilize as she moves from project to project.

Conclusion

Given the skewed distribution of artists' income, how is it that artists are not deterred from entering such an occupation in growing numbers, nor withdrawing from artistic careers as much as would be expected? In order to face the constraints of a rationed labor market, artists have to learn to manage risky careers. Pioneering empirical research by Baumol and Bowen (1966) found that artists may improve their economic situation in three main ways which are not incompatible and may be combined: Artists can be supported by private sources (working spouse, family, or friends) or by public sources (subsidies, grants and commissions from the state, sponsorship from foundations or corporations, and other transfer income from social and unemployment insurance); they can work in cooperative-like associations by pooling and sharing their income and by designing a sort of mutual insurance scheme; and finally they can hold multiple jobs.

Another feature is essential to understand how artists behave under occupational uncertainty. Rewards in artistic jobs are of two sorts: monetary and nonmonetary, the latter being 'psychic income' flows which have in fact been regarded for a long time as an essential dimension of work. Analytically speaking, every job can be regarded as a bundle of characteristics; wage differentials compensate for more or less attractive work and equalize among workers the total monetary and nonmonetary advantages or disadvantages (Rosen, 1986). The benefits derived from nonmonetary income are not of a uniform magnitude. Individual differences in hiring probabilities are, by contrast, not subject to compensation. And an analysis in terms of equalizing differences requires that we adjust the total amount of these benefits according to the job, the level of professional achievement, and the portfolio management of multiple jobholding (Menger, 1989; Throsby, 1996).

Ironically enough, the nonmonetary value of creative work is the genuine fuel of market competition. The intrinsic motivation of each artist, which renders the absence of instrumental calculation rational in the context of creative activity, must compromise with that of all the others. Yet competition through the unlimited differentiation of artistic projects and artworks forbids the artist from seeing the other simply as a competitor against whom he must measure himself, by comparing easily calibrated qualities that would help determine who possesses them in greater quantity. In order to render such competition acceptable, the artist must invent a peculiar conception of his relationship to the audience for which he designates his work and of the action of market intermediaries: He must relativize or negate the sanctions produced by the orientation of audience preferences, and crudely divide the art markets between sectors of production for a vast audience, on the one hand, and sectors geared toward limited consumption, on the other. Such partitioning of the art markets largely contributes to inscribing the mechanism of competition between artists of the same sector into the more striking vision of a mechanism of hypercompetition that radicalizes the opposition between the ways of doing art: one oriented toward profit, and the other toward free and authentic invention. The deformation of the statistical reality of success and failure, as well as the recourse to salient counter-examples, are among the cognitive mechanisms by which artists invent the illusions necessary to provide long-term motivation for their professional commitment.

Asceticism

Abstract

Asceticism is the practice of self-discipline, self-denial, or self-restraint used in order to reach a particular goal. Its origins are found in the activities of Greek athletes and warriors and its practice is found in almost every religion in the world. It was most prominently found in Early and Medieval Christianity and is closely connected to monks. Max Weber developed the sociological study of asceticism and introduced a new type of asceticism – the 'inner-worldly' asceticism of the early Protestants.

Asceticism is the practice of self-discipline, self-denial, or self-restraint in order to achieve a certain goal. This goal can be a physical one, but more often it is a spiritual one. The term 'asceticism' was used originally to refer to ancient Greek athletes who practiced it in order to increase their physical strength and maintain their mental discipline. The term 'ascetic' can be applied to athletes, warriors, artists, and politicians, but it is most commonly applied to religious figures. Ascetics can be found in almost every religion (Pfister, 1927: p. 571). There have been Jewish, Hindu, Buddhist, and Islamic ascetics, but the term is most frequently used in conjunction with early and medieval Christian ascetics and specifically with monks. Different religions emphasize different ascetic practices, but there are five universal traits: fasting, sexual continence, poverty, seclusion, and self-inflicted pain (Heussi, 1936: p. 13; Kaelber, 2005: p. 527). The body is regarded as being evil; thus, there is a fundamental and critical opposition between body and spirit. For Christians, asceticism is the denial of the body; it is a means to an end. The sole goal is to see God. In order to do this, one believes it necessary to 'flee the world,' to leave it as humanly possible without dying (Harnack, 1904: pp. 84, 95, 101–102, 106). The focus here is on early and medieval Christian asceticism and on the modern sociological study of it.

Origins of Asceticism and Early 'Desert Asceticism'

The term 'asceticism' comes from the ancient Greek term 'askesis' ('ἄσκησις') and was used to mean 'exercise,' 'practice,' or 'training.' Karl Heussi, one of the greatest authorities on asceticism wrote that it originally referred to the athletes' practice of exercise or training for sports competition (Heussi, 1908: p. 727; Derrett, 1995: p. 88, Pinsent, 1995: pp. 211–212). The term 'asceticism' was later used to mean a 'mode of life,' 'philosophical life,' or especially 'religious practice' (Liddel and Scott, 1978: p. 257). Asceticism as a type of practice of discipline is found in Aristotle and this notion was carried over into nineteenth century German scholarship. Rheinhold Seeberg's article 'Askese' states that the philosophical use of the term was based upon the athletic term for 'practice' and Otto Zöckler translated 'askesis' as 'Uebung' meaning 'practice' (Seeberg, 1897: p. 134; Zoeckler, 1863: pp. 1–3; Pfister, 1927: p. 570). However, Zöckler emphasized the practice of morality, so he connects its usage to Plato. While both Plato and Aristotle were concerned with ethical conduct, Aristotle believed in happiness and the good life, whereas Plato extolled the notion of rigorous self-control and emphasized the denial of the importance of the world. Thus, the notion of asceticism as possessing a negative attitude toward the world and the body is found primarily in Plato (Dillon, 1995: pp. 80–83). It is found in *The Republic* with need for discipline and ordering of the soul and the city, and it is found especially in the *Phaedo* with its belief that the body tends to corrupt the soul. The world is something to be devalued and denied, and life is not to be enjoyed but should be viewed as a training for death – both important aspects of asceticism for Christian asceticism.

There is some question whether Jesus should be regarded as an ascetic; however, there is no doubt that Paul is considered to have been one (Heussi, 1936: pp. 16–19). For Paul, there was an 'antithesis between *the spirit* and *the flesh*' and his comments on self-control, on sexuality, and on general conduct, all point toward an ascetic doctrine (Brown, 1988: pp. 47–48; Lohse, 1969: pp. 124–126). However, the earliest Christian ascetics were uninterested in doctrine; they were interested in one thing: seeing God and they withdrew from family, friends, and society in order to accomplish this (Gribomont, 1979: p. 217). It was said that those who were visited by people could not be visited by angels (Adam, 1960: p. 1073). These ascetics were the first 'monks'; meaning those who live alone in the wilderness. While monks have long been associated with early medieval monasteries, ascetic monks predate monasticism by several centuries (Heussi, 1912: p. 427; Rubenson, 1995: p. 49). These ascetic monks who withdrew to the desert to live alone were also referred to as hermits or anchorites (Bertholet, 1930: p. 130; Heussi, 1936: p. 54; Adam, 1960: pp. 1072–1074; Derrett, 1995: p. 97). There is no clear evidence regarding who the first of these 'desert hermits' were, but it is relatively clear that they began appearing in the late third and early fourth centuries (Heussi, 1936: pp. 70–76, 109–113). They did not belong to any church and they followed no doctrines or rules; they mistrusted the increasingly powerful Church and they rejected its dictates (Völter, 1900: p. 9; Harnack, 1904: pp. 94, 102–103). They considered the world as a place of temptation, and they regarded the desires of the body as evil. They rejected everything worldly – possessions, marriage, and even honor – in order to live their lives in the service of God (Grützmacher, 1903: p. 217; Harnack, 1906: p. 97). These

monks withdrew from the human world in order to create a new and special world devoted solely to God (Heussi, 1912: p. 427, 1936: pp. 40, 54, 55).

The world was dualistic; it had been created by God but had become filled with devils (Harnack, 1906: p. 113; Heussi, 1936: p. 28). There was the possibility to live a life devoted to God, but the reality was that this life was filled with temptations. These temptations most often came in the forms of devils and demons, and they were everywhere (Harnack, 1906: p. 113; Rubenson, 1995: pp. 51, 53; Ware, 1995: p. 7). While the belief in the devil and demons is found in the New Testament, the belief in them grew considerably during the second, third, and fourth centuries (Harnack, 1906: pp. 108–111). The monks were convinced that these demons sought to inhabit humans and to tyrannize and plague them; thus, it was absolutely imperative that the monks struggled against them (Weiß, 1897: p. 411). Although some ascetics saw devils and demons, most were aware that they were invisible. Satan would tempt them in their own thoughts and their own words (Heussi, 1936: pp. 257, 262–265).

The dualism of God and the world is replicated in the dualism of the soul and body: the soul is spiritual and good, whereas the body is sensible and bad. Asceticism was the struggle against one's own body and the devil (Seeberg, 1897: p. 135; Pfister, 1927: p. 571). These ascetic monks fought against the devil and all of them did so with the power of prayer. But, many of them employed various ascetic practices to drive the demons out and away (Seeberg, 1897: p. 137; Harnack, 1906: p. 110). Some tried to do this by determining how they lived. Some lived in caves, in mountains, and in deserts; the point was to live in isolation. Some ascetics went barefoot and some wore rags. Some wore various kinds of clothing intended to inflict pain if not torture. Some wore nothing at all. Some ascetics ate only roots, others vegetables, others ate insects, but all of them fasted. Some slept on the ground, some standing upright, while others tried to do without any sleep. Some beat themselves, some whipped themselves, and some carried crosses and chains to remind themselves of the temptations of the body and to imitate the suffering of Jesus (Harnack, 1906: p. 115; Zoeckler, 1863: pp. 17–80; Heussi, 1936: pp. 221–229).

It was Tertullian who emphasized the importance of the ascetic life for God and it was he who first wrote about it (Heussi, 1908: p. 727; Preuschen, 1913: pp. 1145–1146). And, it was Antonius who provided us with the earliest form and goals of the ascetic life (Heussi, 1927: p. 399). The ascetic life was solitary, but it is a mistake to think that there were only a few people who left family and friends to settle in the desert. By the beginning of the fifth century, there were approximately 5000 hermits living in one rather small area in Egypt (Brown, 1988: p. 215). It is also a mistake to believe that monasteries developed only in the Middle Ages; the ascetic monks 'fled the world' and its cities only to create a new 'city.' Monasteries were already being formed by the third century (Brown, 1988: p. 217).

Monastic Asceticism

During the third century, a number of changes began to affect the Church. Greek philosophical concepts began to be incorporated into Christian doctrine and the Church began to organize itself (Gribomont, 1979: p. 221). In addition, the notion of asceticism began to play an increasingly important role in the development of Christian ways of life, specifically the monastic life (Harnack, 1906: p. 304; Heussi, 1908: p. 727). Instead of living alone ('kata monas') as anchorites or in small groups, the ascetic monks began to organize and live in communal life ('koinos bios') (Heussi, 1936: p. 115). By the fourth century, monks were living together within walled communities (Heussi, 1930: p. 135). The point of the monasteries was to 'wall off' the monks from the outside world (Arens, 1959: p. 1671). But, it would be a mistake to regard this as a triumph for the Church, because the monks were distrustful of its increasing authority and its expanding hierarchy. The monks were also wary of the Church's perceived increasing accommodation to the world. These newly formed cloisters were intended to further the monks' service to God and to introduce structure to their lives. Their lives continued to be devoted to prayer and sacrifice, but by the beginning of the sixth century, study and work were not only encouraged but expected (Heussi, 1936: pp. 214–220). The earlier anchorites did not beg; they worked. They needed to work to provide for their own food, but they did this individually and with some degree of regularity (Heussi, 1936: pp. 214–217). In this respect, the importance of Benedict of Nursia cannot be underestimated, for he radically transformed the monks' ascetic lives. It was Benedict who was largely responsible for replacing the older, harsh ascetic practices with a highly structured and extremely disciplined life. Now, monks not only lived the life of contemplation ('vita contemplativa'), but also the life of activity ('vita activa'). And, it was Benedict who gave them the new way of monastic life by following his 73 'Rules' for conduct (Arens, 1959: p. 1672; von Lilienfeld, 1993: p. 169; Köpf, 1998: p. 836). Benedict was by no means the first to try to instill order and regularity within the monastic community, but his 'Rules' were probably the most definitive and likely the most influential of any (Prinz, 1980: pp. 34–35). Within two centuries, Benedictine monasteries were being established through many parts of Western Europe – all with the intention of following Benedict's rigorous rules (Prinz, 1980: p. 38). The scope of Benedict's influence is spelled out clearly with the claim that the entire development of Western monasticism from the early Middle Ages cannot be understood without consideration of his writings (Lohse, 1969: p. 226). Bernard McGuinn maintained that Benedict's 'Rules' is "the single most important document in the history of western monasticism" (McGuinn, 1999: p. 27). And, the central focus of the 'Rules' is that the monk is to devote his entire being to God (Lohse, 1969: p. 229).

In Chapter One of his 'Rules,' Benedict discusses the four types of monks; but his interest is primarily in the solitary anchorite, who with God's help, learned to fight the devil, and the Coinobites, who lived together. Benedict evidently believed that establishing a monastery and determining rules was the best way to serve God. While prayer was extremely crucial, Benedict also emphasized the importance of the active life, which included exercises intended to help the monk in his 'ascetic combat' (Fry, 1980: p. 95). In the second and third chapters, Benedict discusses the calling of the Abbot and his function in the monastery. In Rules 4–73, Benedict details the orders that regulate everything about the ascetic life in the monastery, from

the layout of the buildings to the monks' diet to the times for prayer, and especially regarding the importance of work. In Rule 48, Benedict explains that 'idleness is the enemy of the soul' and he instructs the monks to engage in manual labor (Fry, 1980: p. 349). Everyone is to work; even the sick and infirm should be given suitable work (Fry, 1980: p. 253).

The earlier Greeks and Romans had viewed work as lacking intrinsic value, and this certainly applied to physical labor. But, Augustine did not view physical work as a punishment for sin; rather, he believed that it was part of God's creation (Prinz, 1980: p. 68). But, it was Benedict who not only wrote of the necessity of work, but also emphasized its importance (Fry, 1980: p. 70). And, it is not just the importance of work, but the increasing sense of rational order that leads to Max Weber and his social theories of asceticism.

Social Theories of Asceticism

Max Weber was not a religious person and he had no theological interest in the conception of asceticism. He was, however, an astute investigator of human behavior and he sought to understand it within the full range of economics, politics, and sociology. While he examined a wide range of issues, he concentrated on the one defining characteristic of the Western world – its increasing rationality. In his most famous work, *The Protestant Ethic and the Spirit of Capitalism*, Weber attempted to draw a correlation between asceticism and capitalism. He did not try to prove this and he acknowledged that what he offered was only a sketch. However, the *Protestant Ethic* does contain a fascinating study of one type of asceticism – 'inner-worldly asceticism' (Köpf, 1998: p. 837; Kaelber, 2005: p. 529). This type of asceticism differs in fundamental ways from traditional Catholic asceticism: It is Protestant, it is 'world rejecting,' and it is 'active.'

Asceticism had been closely associated with Catholicism in general and with monks in particular. Weber's analysis of Protestant asceticism showed that there were clear differences between the types of asceticism. First, while monks were not enthusiastic about Church Doctrine and they occasionally even rebelled against it, they were devoted to the Abbot's authority and they were comfortable in the monastic environment. In contrast, the early Protestant ascetics rejected any type of doctrinal authority and believed only in the authority of the Bible. Second, while the early Protestants lived in communities and participated in a Church, they continued to maintain that religious life was not communal but was intensely personal. This is not to say that Weber believed that all early Christians adhered to the same beliefs. On the contrary, for him, one of the most distinguishing differences between Luther and Calvin was the differing conceptions of God. Luther's God is closer to the Catholic God in that Luther's notion is of a loving father, whereas Calvin's deity resembles the angry and vengeful God of the Old Testament (Weber, 1996: pp. 58–61). Moreover, Luther still tended to believe in the Catholic tradition of sin and redemption, but Calvin rejected such notions. For him, God ordained that a select few were chosen, whereas the majority was damned. Calvin's Doctrine of Double Election held that God had preordained everyone; as a result no one could be certain whether he or she was among the Elect. This uncertainty caused the Calvinists extreme anxiety and pushed them into extreme inner loneliness. Unlike Catholics, the Calvinists could not seek comfort in a sacrament or a church (Weber, 1996: pp. 62–66). What it did prompt them to do is to work, with the conviction that work was solely for the greater glory for God (Weber, 1996: pp. 66–71, 73–74, 78).

The second major difference is that the Catholic monks sought to 'flee the world,' whereas the early Protestants 'rejected the world.' This notion is not only important for Weber's *Protestant Ethic* but also crucial for Weber's entire sociology of religion. Thus, Stefan Breuer is correct to call it world-rejecting ('Weltablehnung') a "key concept in Weber's sociology of religion" (Breuer, 2001: p. 227; Mulert, 1913: p. 1914; Weber, 2001: p. 324). While Catholics and early Protestants regarded the world as a place of temptation, only Catholic ascetics sought to flee from it. In contrast, ascetic Protestants sought only to deny certain aspects of it and in certain respects even had a certain 'world-enjoyment.' Weber did not mean that they relished life, but he did believe that they 'valued life as a task' (Weber, 1996: p. 48). They did not work for pleasure; rather, they viewed their work in the world as their service for God. They did not create wealth for themselves; they did it solely for the benefit of God. Weber notes this paradox applies to the rational ascetics, but he also points to another paradox that pertains to the monks: as individuals they live lives without possessions, but the monasteries and churches that they inhabit and serve are filled with them (Weber, 1989: pp. 489–490).

Weber acknowledges certain similarities between the ascetic monks and the ascetic Protestants and he allows that Benedict and his successors were responsible for introducing regulations into monastic life (Weber, 1996: p. 78). However, the monks did not lead a rational life and they withdrew behind the walls of the monastery in order to 'flee the world.' In contrast, the early Protestants were 'inner-worldly' ascetics; that is, they chose to remain in and participate within the world, but as ascetics. Weber emphasized that these ascetics practiced rigorous and systematic self-control and he stressed that this self-control was rational and methodical (Weber, 1996: pp. 77–80).

The third major difference is Weber's distinction between asceticism and mysticism. Weber never provided a complete theory of asceticism and he chose to contrast asceticism with mysticism (Adair-Toteff, 2010: p. 109). This should not be taken to mean that Weber did not understand or appreciate mysticism, because he did (Adair-Toteff, 2002: pp. 339, 352–353). In the *Protestant Ethic*, Weber noted that the Lutherans were like the Catholic mystics in that the ultimate goal for both was the 'unio mystical' – the 'mystical union' with God. And, he stressed that both engaged in passive contemplation in order to achieve this union (Weber, 1996: pp. 71–72). In his later 'Zwischenbetrachtung' Weber sets out his 'theory of the steps and directions of religious world-rejection' and it is there that he spells out in more detail the opposition between active asceticism and contemplative mysticism (Weber, 1989: p. 481). In fact, he regards the contrast between the ascetic and the mystic as being a 'polar opposition.' He maintains that the ascetic regards himself as a 'tool' or 'instrument' of God and it is his duty to be active. In contrast, the mystic is a 'vessel' and it is imperative that he remain passive and quiet in order to listen to God (Weber, 1989: p. 482). Weber acknowledges that the distinction between ascetic and mystic can collapse but he insists that the

opposition persists because the former is inherently rational while the latter is predominately irrational (Weber, 1989: pp. 482–483). The rational ascetic seeks to control the world by imposing form; the irrational mystic seeks to flee the world into a totally 'formless experience' (Weber, 1989: pp. 501, 507).

The account of asceticism provided by Weber seems compelling, but it can be challenged on several fronts. First, his 'polar opposition' between ascetics and mystics is questionable, both in a historical and theoretical way. Throughout history, there have been individuals who have been regarded as being 'ascetic mystics' beginning with Paul (Romans 8: pp. 7–8; Derrett, 1995: p. 93; Lohse, 1969: p. 172). Weber was quite familiar with the medieval German mystic tradition, which was attracting scholarly attention. Heinrich Seuse, a follower of Meister Eckhart, was a mystic who wrote about the 'unio mystica' and who adopted many of the practices of the 'desert ascetics,' including fasting, wearing rough and irritating clothing, and sleeping on freezing cold surfaces (Wentzlaff-Eggebert, 1947: pp. 6, 18, 28).

Asceticism and mysticism are also closely connected theoretically. Evelyn Underwood, whose *Mysticism* first appeared in 1911, wrote about the connection between ascetic self-discipline and the striving for mystical visions (Underwood, 1990: pp. 224–277). Karl Heussi, the leading authority on asceticism, maintained that asceticism is the preparation for the reception of God's grace and the unification with him (Heussi, 1936: pp. 45, 266–269). And, Bernard McGuinn, the author of the multivolume work on mysticism frequently connects mysticism with asceticism (McGuinn, 1995: pp. 109, 110, 137, 144–148; McGuinn, 1999: pp. 26–29).

The preceding criticism focused on Weber emphasizing the differences between asceticism and mysticism, whereas there is another one that addresses Weber minimizing the differences between monastic life and industrial capitalism. This complaint is found in Hubert Treiber and Heinz Steinert's *Die Fabrikation des zuverlässigen Menschen* (Treiber and Steinert, 1980) but it receives its fullest discussion in Lutz Kaelber's *Schools of Asceticism*. Kaelber's account is important because he correctly sets out Weber's thesis about rational asceticism by emphasizing the two fundamental traits: (1) 'restraint and self-control' and (2) 'the systematic control of this plan' (Kaelber, 1998: p. 3). But, it is even more important because he examines two medieval ascetic movements that basically embody these traits: the Waldesians and the Catharists. Kaelber does not condemn Weber for ignoring these; instead, he compliments Weber for at least acknowledging that there are certain similarities between monastic life and the rational ascetic life and he provides an account of western Christianity that Weber was unable to do because of his premature death. Weber may not have fully understood asceticism, but he clearly recognized many of its critical features. Moreover, he was the first to understand and appreciate the revolutionary power of 'inner-worldly' rational asceticism.

Conclusion

The practice of asceticism is found in various forms throughout history, but its two most studied forms have occurred in Christianity. It was found first in the 'world-fleeing' form in the early desert ascetics and then in medieval monks, and then in the 'inner-worldly' form of some of the early Reformers. While most of the adherents to these forms believe in a dualism of soul and body, the 'world-fleeing' ascetic denigrates the world while the 'inner-worldly' ascetic accepts the world and works in it in order to praise God. All reject the notion of the material enjoyment of wealth, but the Puritan ascetic believed that wealth gained through hard work was a sign that one was a member of the Elect.

The greatest impetus for someone to become an ascetic monk was the realization of one's own sense of sin. This is not the recognition of doing one or two sinful deeds; rather, it was the steady and vividly self-conscious sense of continual sin (Heussi, 1936: p. 190). Without that sense of sin, there is little reason to engage in asceticism. It was Adolf von Harnack, one of the greatest of the Protestant Church historians, who indicated the reasons for the decline in asceticism. He suggested that when the belief in sin and guilt is replaced by the Paulinian-Augustinian trinity of 'faith, love, and hope,' asceticism no longer has such a compelling power over people (Harnack, 1916: pp. 156–158). But, for those who despise the body and renounce the world, asceticism will always be a way of life.

Abstract

China's modernization brings to the fore the challenges of nationalism, state building, and social integration. This article traces the development of Chinese society and culture since the dissolution of the Qing empire in 1911 through the collective period after 1949 and the reforms since 1978. The article focuses in particular on the changes in the social, cultural, political, and ethnic diversity of Chinese society; the impact of market capitalism on life, work, and social organization; the impact of China on the world and the world's impact on China; and the challenges currently facing Chinese society.

Introduction

Modern China is a country that is heir to the vast empire conquered by a non-Chinese group called the Manchus, whose origins were in what is now China's northeast, or Manchuria. The Qing dynasty that they established lasted from 1644 to 1911. The Manchus incorporated in their empire large non-Chinese territories, such as Manchuria, Mongolia, Xinjiang, Tibet, and Taiwan. All that these territories had in common was some form of allegiance to the emperor, regardless of their culture, ethnic orientation, religion, or even political system.

The heritage of empire makes contemporary China a political entity that struggles to find a political form. This task is made even more difficult by the legacy of Western and Japanese imperialism and the Cold War during the last two centuries. Not only Taiwan (asserting itself as an independent republic), Hong Kong, and Macao (with the status of special administrative region) but also Tibet, Xinjiang, Inner Mongolia, Ningxia, and Guangxi (all autonomous regions) claim or have been given various degrees of autonomy or independence from the government of the People's Republic of China. As a modern nation-state, China therefore is anything but a finished product, and is probably best described as a work in progress.

China is also a civilization, connected to but by no means coterminous with any contemporary political unit that calls itself China. Viewed from this angle, China and being Chinese are not just a matter of belonging, but also of becoming. This has at least two aspects. Chinese culture, goods, influence, and people have for centuries fanned out far beyond the reach of the Chinese state, mixing and mingling with other cultures and civilizations in a variety of settings all across the world.

This article asks three broad questions. What unites and what divides China as a country, society, and culture? What are the distinguishing features of China's developing modernities? What is the impact of globalization on China, and what impact on the world do Chinese society and culture have? Below, each question will be discussed in a separate section. The article will draw mainly on recent anthropological research, supplemented with work by sociologists, social geographers, historians, and political scientists.

Anthropologists of China have long been drawn to China, fascinated by its scale and complexity. Yet for most of the twentieth century, anthropologists mainly tended to view China through village studies, communities that were seen as largely self-contained and bound together by the bonds of family (major ethnographies include Ahern, 1973; Cohen, 1976; Lin, 1998; Wolf, 1968). Connections between these communities existed, of course, but were seen as largely limited to traditional patterns of trade (Skinner, 1964), intervillage marriage and supralocal kinship organization (Freedman, 1958, 1966; Fried, 1953), and religious networks (Sangren, 1987). Anthropologists for the most part ignored the impact of the traditional or early modern state, with the exception of some work on Chinese towns and local elites (Fei, 1953) and the interactions between Chinese popular, official, and organized religion (Feuchtwang, 1977; Yang, 1961). This tendency was strengthened by the fact that, until the early 1980s, the People's Republic did not allow foreign researchers in. China anthropologists had to be content with proxy fieldwork in Taiwan or Hong Kong or among overseas Chinese, where they sought to reconstruct prerevolutionary Chinese society from artificial slices of culture carefully dissected from complex and rapidly modernizing societies outside China itself. (An excellent overview and discussion of the anthropology of China of this period is given by Steven Sangren in his article on China in the first edition of this encyclopedia (Sangren, 2001).) It has only been in the last 30 years that China anthropologists have squarely dealt with contemporary society and culture in the People's Republic.

Unities and Diversities

China is a continent-sized country. Since the first unification of China in 221 BCE, ruling dynasties expanded and unified their empires either directly through warfare, tribute relationships, and the recognition of indigenous rulers or indirectly because of the effect of migration, intermarriage, trade, road building, land reclamation, and cultural assimilation. As a result, over the centuries China incorporated a rich variety of peoples and cultures. These peoples adopted aspects of Chinese culture, such as ancestor worship, cosmology, religion, or gender relations, gradually translating differences between Chinese and non-Chinese into part of the endless diversity of Chinese culture. Other groups, however, stayed beyond imperial rule, either by choice or exclusion. These non-Chinese 'barbarians'

living within or immediately adjacent to the empire owed neither tax nor corvée labor, but could also not count on imperial protection and the opportunities for upward mobility that Confucian education offered their elites. These processes have been best documented for parts of China that were firmly incorporated during the last dynasty of the Qing, such as Taiwan or Yunnan (Brown, 2004; Giersch, 2006; see also the articles in Crossley et al., 2006).

Early Chinese nationalists around the turn of the twentieth century imagined the new Chinese nation as the successor of the empire, thus opting for a 'maximal' definition of the nation and its territory that required from the onset recognition and accommodation of non-Chinese groups and territories in the new nation (Crossley, 2005). The Chinese nation built after the fall of the Qing in 1911 therefore incorporates two very different, at times even conflicting, narratives. The Chinese nation was to be the home of the Chinese, a safe haven and instrument to undo the injustices of Manchu alien rule and 'national humiliation' by Western and Japanese imperialists after the Opium Wars. The nation would unify all Chinese and restore China's rightful place in the world. But the Chinese nation was also imagined as the reincarnation of an empire consisting of groups no longer glued together by dynastic rule, but by the cultural, economic, and political dominance of the Han majority.

After coming to power in 1949, the Chinese Communist Party (CCP) continued to embrace these two conceptualizations of the nation. The CCP views China as a composite 'multination country' (*duo minzu guojia*), consisting of 55 'minority nationalities' (*shaoshu minzu*) and one majority nationality, the Han. The identification of these nationalities took place mostly in the 1950s; since then they have remained largely fixed with individual membership determined by birth. Minorities were given certain rights and privileges (including the right to practice their own culture and religion) and also a degree of self-administration (autonomy) of the provinces, prefectures, or counties where they lived (Heberer, 1989).

In contradistinction to the many different minorities, China's majority population is universally called Han. Yet their culture and language display a rich diversity, predominantly rooted in regional variety (Cantonese, Fujianese, Pekingese, Shanghainese, etc.). In addition, Han Chinese are also divided along ethnic (cf the Hakka of Southeastern China, see Constable, 1996) or religious (cf Muslim Chinese, see Gladney, 2004) lines that uncomfortably straddle the divide between the Han majority and the non-Han minorities. China's minority policies thus not only emphasized the minority–majority distinction, but also put an almost total ban on the political expression of regional or cultural differences among the Han.

The recognition of minority nationalities is part of an elaborate administrative system that was set up after 1949 to regulate and manage forms of diversity: religious, cultural, and ethnic. This system is supervised by the CCP through its United Front Department. After the turmoil of the Cultural Revolution, the system was reinstated and even strengthened and it continues to play an important role until the present day, turning forms of diversity into bureaucratic statuses that come with highly regulated rights, duties, privileges, and restrictions. In addition to 56 nationalities, China thus has practitioners of five recognized religions (Catholicism, Protestantism, Islam, Buddhism, and Taoism; Yang, 2012); compatriots from Hong Kong, Macao, and Taiwan; overseas Chinese; returned overseas Chinese and their dependents (Barabantseva, 2011); and even foreign friends and guests (Brady, 2003).

During the collective period (1949–78) society was forced into the straightjacket of a socialist planned economy. Industry, agriculture, trade, and services were nationalized or collectivized. The establishment of the household registration system, unified job allocation, and rationing of foodstuffs and many other consumption goods tied people to one place: the rural population in their villages as members of their collective team, brigade, and commune (Heins Potter and Potter, 1990) and the urban population in their town or city of residence as members of their 'work unit' (*gongzuo danwei*; Bray, 2005). Except for times of great upheaval, such as the famines of the Great Leap Forward between 1958 and 1962 or the political mayhem of the Cultural Revolution between 1966 and 1969, mobility was subject to bureaucratic allocation, either as part of the economic plan or through more informal arrangements made by individual work units or collectives.

After 1949, diversity became much less prominent and politically relevant in Chinese society than it had been before. Minorities, religions, overseas Chinese, and foreigners were contained in their own separate places and spaces. Social life mainly took place in the main building blocks of society, urban neighborhoods and work units and rural villages and collectives. Due to the restrictions put on mobility, Chinese from different places and backgrounds mixed and met much less frequently. Furthermore, with the establishment of a unified administration under the leadership of the Communist Party, native place (with its associated linguistic, cultural, and religious aspects) ceased to be a principle of organization and vehicle of political participation among city populations (about pre-1949 China on this point, see Rowe, 1989).

This picture of strict regulation and containment of social life in general and diversity and mobility more in particular changed after the start of reform in 1978. This happened slowly at first, but quickly gained speed, particularly during the second phase of reform that started in 1992–93. In the countryside, the reforms unleashed the enormous entrepreneurial potential of China's rural population that had remained bottled up for 30 years. In the early 1980s, land was decollectivized, giving farmers not only much better incentives to step up agricultural production, but also the freedom to decide whether to stay on the farm, start another business, work for a local enterprise, or move elsewhere in search of work or business opportunities. In the 1980s, millions of farmers found their way to China's cities, working in construction, manufacturing, petty trade, and other jobs that the established city population, entitled as they were to state employment, did not have or did not want to do. In the 1990s, reforms targeted the urban sector and a further opening up to the world economy. The result was an urban investment boom and the rapid growth of the export-processing sector. At the same time, the rural population suffered from declining agricultural prices, land expropriation for development projects, deteriorating services, and increasingly rapacious government (Bernstein and Lü, 2003). As a result and despite an initial surge in urban unemployment, the 'floating population' (*liudong renkou*) of rural–urban migrants grew well to over 100 million, reaching around 200 million, or about one-sixth of China's total population of 1.3 billion, in the 2000s.

Members of the floating population are second-class citizens. The barriers to internal migration thrown up between cities and the countryside by the household registration system are in many ways comparable to the impact of national borders on international migration. Despite that fact that by now many rural migrants have lived in a city for many years, they continue not to be denied the entitlements of permanent city dwellers like a house rented from or purchased from the work unit, health care and health insurance, and education. Rural migrants therefore continue to be tied to the soil of their village of origin: their key entitlements and obligations continue to be had not where they happen to live but where they are from and where one or more members of their family (parents, spouse, or children) quite often continue to reside and work the land (Chan, 1994).

Rural–urban migration brings people from many different places together in China's larger and smaller cities, (re) producing forms of diversity that could not develop during the collective period. However, prerevolutionary forms of organization and representation (native place organizations and guilds) have not reappeared, and migrants are largely powerless in the face of the established population and local authorities. The best known case is 'Zhejiang village' (*Zhejiang cun*) in Beijing in the 1990s, a community of often very successful traders and entrepreneurs from the area around the city of Wenzhou in Zhejiang province. The Beijing authorities deemed their presence a nuisance and even a threat. Throughout the 1990s, the police repeatedly raided the area, demolishing houses, the wholesale market, and workshops that made up the 'village' (Xiang, 2005).

Migration and mobility are by no means limited to rural–urban migration to China's industrial centers in the eastern coastal areas. Politically very important is the long-standing migration from China's interior to peripheral, originally non-Chinese territories, such as Tibet, Xinjiang, and Inner Mongolia. Much of this is state-planned or state-induced, an element in the strategic incorporation of these areas into the Chinese nation-state (Rossabi, 2004). The reforms period has added increasing flows of nonstate planned migration of entrepreneurs, skilled workers and professionals, farmers, traders, and tourists (Halskov Hansen, 2005; Schein, 2000). Non-Han Chinese are now becoming minorities even in many of their own autonomous areas, a politically combustible development especially in Xinjiang and Tibet, where the Chinese presence is the most controversial and where tensions have traditionally been high.

During the reform period, Chinese not only started to migrate to destinations inside the country itself, but also abroad. In the nineteenth century after the defeat by Western imperial powers during the Opium Wars of 1842 and 1860s, China had been forced to open up the outside world. This starting some of the largest emigration flows of the century, with Chinese fanning out to destinations all across the world (McKeown, 1999). In 1949, China quickly shut itself off from further emigration, but emigration quickly rebounded in the 1980s, reaching levels in the early twenty-first century unprecedented even at the peak of emigration 150 years earlier. China now is one of the most important sending countries. Apart from sheer numbers, the most important fact about Chinese international migration today is the diversity of migratory flows. Migrants now hail from all over China, and include business and government expatriates, investors and entrepreneurs, students, professionals, contract workers, unskilled job seekers, and family migrants. Added to this must be the vastly larger number of Chinese who travel abroad for shorter periods as tourists or visitors on business, on exchange programs, or as members of delegations. The world is indeed becoming a Chinese space, with long-term emigration being a vital, but by no means the only component (Chu, 2010; Fong, 2011; Nyiri, 2010).

More recently, international migration to rather than from China has been added to the mix. Since the mid-1990s, a rising number of foreigners live in China, many of whom do so long term or even permanently. These immigrants are attracted by the opportunities of investment, employment, trade, or business. Others come to China for the promise of a better life or a politically more stable environment. International migrants still are only a minute fraction of China's huge population, but according to the 2010 census their absolute number has already surpassed the 1 million mark. Moreover, foreigners are highly concentrated in specific parts of the country, such as Guangzhou, Shanghai, or Beijing. In these places, foreigners have become a long-term and important aspect of the urban landscape, contributing to the increasing diversity of cultural, religious, linguistic, and even political life. In the last 10 years, China's large coastal cities have become global cities, cosmopolitan hubs that attract people from all over East and Southeast Asia and beyond (Pieke, 2012).

Despite the persistence of the household registration system and minority policies that continue to be predicated on the assumption that it is the norm that people stay where they belong and have specific ascribed and unalterable statuses, Chinese society has changed almost beyond recognition over the past 20 years. Indeed, the paradigms of migration and diversity no longer seem adequate to describe many of these developments, especially in the last 10–15 years. Social and spatial mobility have become increasingly normal, an enduring aspect of life in China. A new generation of rural migrants – often the children of parents who were migrants themselves in the 1980s or 1990s – no longer seems content with temporary employment in the expectation of an eventual return to the village. Indeed, it is increasingly difficult to distinguish these highly rural migrants and city high school and college graduates who travel across China in search for work and a career, often staying in one place for no more than a few weeks or months (Siu, 2007). China is moving rapidly in the direction of a nationally integrated job market, where regional and rural–urban differences no longer define and limit one's chances, aspirations, and destinations.

Unfolding Modernities

The gradual dissolution of the work units and village collectives has broken down many of the old barriers and certainties of socialist society. In their stead, a society is developing where the population consists of families, households, and individuals who are free to achieve their life goals in ways and places of their own choosing. We should not mistake this for a gradual demise of the socialist system under the impact of market

capitalism: in China, capitalism and socialist governance have proved to be symbiotic rather than antagonistic (Pieke, 2009). Yet despite the strengthening of the regime of the CCP and the absence of a multiparty democracy and human rights, substantial gains in personal, economic, and even political freedom have been real and sustained.

China has become a highly aspirational society with rapidly growing and increasingly wealthy and self-conscious middle and upper classes (Goodman, 2008). For many such middle class Chinese, especially in the eastern coastal regions, modernity is both an achieved status and a promise of a better future. A belief in the opportunities to move up in the world by dint of hard work, thrift and ability is widely shared among the population, even among the most disadvantaged groups and in the face of rising inequality and the absence of a level playing field (Whyte, 2010). The state promotes a discourse on the greater or lesser 'quality' (*suzhi*) of the population, individuals, and groups. The concept of 'quality' quite deliberately conflates many different vectors and explanations of success (education, wealth, genetic makeup, rural or urban residence, to name just a few). 'Quality' discourse puts the blame for backwardness on those who are deemed backward. It points to a strategy to achieve national strength and modernity that raises the 'quality' of the population, in effect telling the losers of the reform process to catch up or else be permanently left behind (Anagnost, 2004).

Perhaps the most visible example is education. Rising standards of living and the marketization of education have impelled hundreds of millions of middle class families to invest all their resources in the education of their one child. The aim is to score high enough in the nation-wide college entrance examination to get into a good university, and beyond that perhaps the opportunity to study abroad. For many families, education has become a bottomless pit that they will continue to throw money in, often regardless of the expected return on the education received, a will to elite status with strong echoes of a Confucian past (Fong, 2004; Kipnis, 2011).

Housing is another aspect of the fundamental changes that have taken place. Rural Chinese always owned their own homes, but in the second half of the 1990s urban work units ceased to rent highly subsidized housing to their members. China became a nation of home owners. Residence now reflects choice, wealth, power, and status, leading to a spatial sorting of the population in different types of neighborhoods that looks more and more like capitalist societies (Zhang, 2010). Quite often, this is anything but a smooth process. Demonstrations, petitions, and law suits against the demolition of old neighborhoods or the appropriation of rural land for development are rife; indeed, land and housing demolition are the most important issue of political contestation in China today (Hsing, 2010; O'Brien and Li, 2006). In conjunction with this shift, the government has responded to the weakening of work units to building up residential 'communities' (*shequ*) as a key interface between local government and the population. In these new communities, local police, government agencies, property management agencies, and home owners associations are jointly responsible for local governance (Read, 2012).

In rural China, the hand of government weighs less heavily as in urban areas. Villages are no longer collective units of agricultural production, but continue to be central as units of residence, land rights, and other entitlements. In the 1980s, villages played a crucial role in fostering enterprises, either privately or collectively owned; some of the more successful among them evolved into genuine business conglomerates with a diverse portfolio of holdings. Although the age of such 'super villages' seems to have passed, villages located close to (or even enveloped by) cities control valuable land that they can turn into a substantial source of income for the village and its members (Hsing, 2010; Siu, 2007). After the reforms, many villages have reinvented prerevolutionary ways to recreate and celebrate their sense of community. Fueled by the increased wealth brought by the reforms, patrilineal kin groups, Christian churches, popular religious temples, festivals, and celebrations have become crucial aspects of village life and governance, with formal village heads or party secretaries frequently doubling up as lineage leaders, temple elders, or organizes of fairs, festival, or ritual celebrations (Ashiwa and Wank, 2009; Chau, 2006; Jing, 1996; Tsai, 2007).

In 1949, China had only just started on the road to nation building. By 1978, after 30 years of unification and political integration, China had progressed immeasurably farther. A unified spoken and written national language was now taught in most high schools and universities across the country. An elaborate network of national and local media (newspapers, radio, and television (TV)) reached into virtually all areas and households. A sense of Chinese identity was shared across the country regardless of the many local, ethnic, and religious identities that existed. Yet it was only the generations after the start of the reforms that fully became nationally Chinese. For the first time, large numbers of children grew up speaking standard Chinese (Mandarin) as their first language rather than a local dialect. Travel, tourism, and migration created spaces and experiences that encompassed China as a whole (on tourism, see Nyíri, 2006). The commercialization of the mass media meant that national TV began to cater to popular tastes, creating audiences of hundreds of millions of households for shows, soaps, and movies. More recently, the Internet and social media have united Chinese across the country into a plethora of virtual communities around any issue, interest, or hobby imaginable. The hand of government censorship usually does not weigh as heavily as is often thought and largely is limited to attempts at organizing collective action or explicitly political activities (Yang, 2009; Zhou, 2006). Against this background, it is not all that surprising that the 1990s and 2000s have been the age of the growth of popular nationalism, which sometimes is virulently jingoistic or even racist. Some of this is no doubt due to careful nurturing and manipulation by the regime, but a more important explanation seems to be that for many people only in this era China began to exist and be experienced as a lived-in reality (Gries, 2004).

The erosion of work units and collectives, social and spatial mobility, and the emergence of a national space have been complemented by the individualization of Chinese society, or, as Chinese sociologists sometimes put it, Chinese have changed from being "people of work units" (*danwei ren*) to "people of society" (*shehui ren*). Individualization in China is sometimes linked to a deterioration of social norms and a lack of social responsibility and at odds with traditional Chinese culture that emphasizes group membership (especially the family) and the relatedness of the social person (cf Yan, 2010).

Norms of reciprocity and social obligations, already under pressure during the collective and early reform period when they often deteriorated into the instrumental use of "personal connections" (*guanxi*, see Yang, 1994), are now thought to be further in decline. Market exchanges and contractual obligations backed up by the rule of law leave less space for favoritism and the manipulation of personal relations (Gold et al., 2002). In the private sphere, the traditional Chinese emphasis in the Chinese family on the obligations between parents and children has given way to personal choice in marriage and the primacy of conjugal relations between husband and wife (Yan, 2003).

In terms of gender relations, the reforms have proved to be a mixed blessing. While the Maoist period was certainly not a feminist utopia, increasing labor participation and education of women nevertheless meant a huge improvement. In certain respects, the reform period further improved the position of women, especially in the cities. With the one-child-policy (Greenhalgh and Winckler, 2005), many couples are raising a single daughter and cannot and do not want to treat her any different than they would if their single child had been a son. However, in many other places, things were not quite so simple. Rural couples in need of a son to continue the family line and as security for old age often feel forced to abort, abandon, or not register a baby daughter. China's sex ratio is now dangerously skewed within some places 150 or so men for every 100 women. Tens of millions of children and young adults, many more of them women than men, were born illegally and have none or only very few rights.

The forces of the market and social inequality also impinge on gender relations. Rural-to-urban migration has provided a way for many young rural women to become socially and financially independent from their parents, husbands, or parents-in-law. However, many of these women find themselves into potentially very exploitative situations as live-in domestic help, in sweatshops, or in the sex industry (Yan, 2008; Zheng, 2009). The wealth, social inequality, and scarcity of women generated by the reforms and the one-child-policy have led to many forms of commercialization and commodification of women and sexuality. These include a steep hike in bride-price for marriage, concubinage, prostitution, and smuggling or trafficking of women. This is rapidly developing a transnational dimension. Women from, for instance, North Korea or Southeast Asia come to China to marry Chinese men, while others end up in the sex industry. Conversely, married Taiwanese or Hong Kong men are known to maintain a mistress in Shanghai or the Pearl River Delta (Grillot, 2012; Shen, 2005).

Modernization, wealth, individualization, and social and spatial mobilities create a whole new diversity of life styles. Like in other developed societies, these life styles are techniques of the self that are driven personal choice and inclination rather than ascription and are informed by fashion, mass media, peer groups, and popular culture. Some of these life styles define communities of belonging within the anonymous environment of China's megacities; others are a matter of individual consumer choice and identity construction (Gerth, 2010). Sexual orientation and preference (Jeffreys, 2006, modern art or pop music De Kloet, 2010), and conversionary religions (Buddhism, Christianity, syncretic sects Goosaert and Palmere, 2011) are only some examples. The vast majority of such communities have little if any interest in political participation or activism. Nevertheless, the example of the Falun Gong demonstrations in 1999 shows that their impact can be very sudden and substantial, enough to trigger immediate suppression from the authorities.

China's modernization of the last 30 years has been an unprecedented story of sustained success. Chinese have become immeasurably wealthier than they have ever been. Yet some real problems have emerged that in the long term threaten to undo many if not most of the quality of life gains of reform. Most elusive are the twin issues of environmental degradation and long-term demographic imbalances. Air, water, and soil in many areas are now so polluted that they have become virtually uninhabitable. In many places, the environment has become a major cause of local political contention; added to this should be the rising discontent about food safety, particularly after scandals with tampered baby formula in 2006 and 2008. The Chinese authorities are now increasingly aware that a "pollute now, pay later" attitude no longer works and an impressive regulatory framework has been put into place. Yet genuine and sustainable solutions of the many problems have to be weighed against the competitive advantage of major sectors of the economy. In other places, the damage already is irreparable or, perversely, pollution has become so much part of life that the local population either are ignorant of its harmful effects or has become so dependent on payoffs from polluting factories that they actually resist change (Lora-Wainwright, 2009; Weller, 2006; Yan, 2012).

Demographically, China lives on a time bomb. Until 2013, the economy benefited from a demographic dividend (relatively few old and young people and thus a large working-age population). This dividend has now run out. Henceforth, there will be a population deficit with relatively small cohorts of young people entering the labor force and relatively large cohorts of pensioners leaving it (Park et al., 2010). This problem is only in part a normal aspect of the demographic transition that all developing countries go through. It is made much worse by 30 years of strict, state-mandated family planning that still has not been abandoned for reasons that with each passing year become increasingly obscure (Greenhalgh, 2008).

Whether China is able to overcome the challenges that lie ahead is not just a Chinese problem. China's global impact is now such that what will happen there will be felt by us all. A stable, prosperous, and confident China is in everybody's best interest.

This article is a revision of the previous edition article by N. Abelmann, volume 12, pp. 8159–8162, © 2001, Elsevier Ltd.

Abstract

This article examines the historical development of the anthropology of Korea and the Koreas from the nineteenth century to the present, highlighting the shifting multinational character of this anthropology over time. It examines the contexts of colonialism and the predominance of social anthropological village studies in the years after 1945, while devoting its greatest attention to trends in sociocultural research on both Koreas over the past two decades.

Late Nineteenth Century and Colonial Origins of the Anthropology of Korea

With respect to US anthropology, Korea had a greater role in late-nineteenth-century evolutionary ethnology, institutionally based in museums, than it would in the immediate wake of the early twentieth century disciplinary turn to long-term fieldwork as a defining research method. The 1882 treaty that established diplomatic relations between the United States and the kingdom of Chosŏn (i.e., Korea) coincided with a general expansion of collecting activity at the United States National Museum of the Smithsonian Institution, the dominant anthropological institution of the era. More specifically, it coincided also with a joint program between the Smithsonian and the US Navy to train young naval officers in scientific techniques and employ them for museum purposes. The first major anthropological collection of Korean materials to arrive in the United States came courtesy of a product of this program, John B. Bernadou. Drawing on this and on other collections of the late 1880s, National Museum Curator of Ethnology Otis Mason (1886: 115) offered an initial gloss of the significance of Korean objects as "a human exemplification of the survival of whole genera of industries and customs, while in surrounding regions these have been swept away or transformed." Mason's location of Korea's importance in relation to E.B. Tylor's notion of evolutionary survivals, but also simultaneously in universal ('human') and regional terms, bespoke a larger ambivalence that attended the evolutionary anthropological understanding of East Asian societies in this period. One resolution would come almost a decade later in the form of the first book-length study of Korea in the US anthropological tradition, Stewart Culin's *Korean Games*. Culin's book stemmed from a joint project with his fellow anthropologist and close friend Frank Hamilton Cushing, whose research focus was on the US Southwest. Together, Culin and Cushing sought to demonstrate parallel sequences of the evolutionary development of games of chance from practices of divination in East Asia and North America, and thus to make a strong argument for 'independent invention' – the like working of a (universalized) human mind in similar circumstances – over diffusion as a primary explanation for the occurrence of similar customs or artifacts in widely separated areas. Even as Korea was thus being enlisted into metropolitan anthropological theory, a generation of missionaries, travelers, and diplomats resident in the country itself were producing texts that, while often quite judgmental, were also more descriptive and ethnographic in feel (Chun, 1999: 41–42). Ironically, it is these works, more than those of the nineteenth-century US anthropological establishment, that have tended to be appropriated as useable precursors for more ethnographic anthropologies that followed the eclipse of the evolutionary paradigm.

Yet from this early moment, Korea has also offered a contrast to situations in which a dominant national tradition of anthropological analysis has grown up within relatively settled colonial relations, as, for example, in the case of British social anthropology in Africa or studies of Native Americans in the United States. The relative lateness of colonialism in Korea contributed to a situation in which the anthropology of Korea was from the first deeply multinational in its authorship. French, Russian, British, and German anthropologists also produced a volume of scholarship. The foundation of the Tokyo Anthropological Society under Tsuboi Shōgorō in 1884 was followed around 1890 by the first appearance of articles on Korea in its journal, *Jinruigaku Zasshi*, setting the stage for subsequent research during the colonial era (Chun, 1999: 42–43). At the same time, Korean intellectuals of this period, in their attempt to imagine and configure national modernity under the shadow of imperialist encroachment, drew both on extant local argumentative traditions and on imported frameworks such as evolutionism and Social Darwinism, producing many writings with an auto-anthropological character (for the example of Ko Ŭijun, see Chun, 1999: 35–41). At moments, the dialogue of Korean indigenous scholarship and proto-institutional international anthropology was quite literal. The intellectual Yu Kilchun toured the United States in 1883 as part of an official study mission and then stayed on to attend US schools, living for a period with the natural historian, archaeologist, and ethnologist Edward S. Morse near Salem, Massachusetts. Yu went on to publish *Sŏyu kyŏnmun* (*Observations on a Journey to the West*), one of the most important late-nineteenth-century Korean accounts of world geography, history, and Western governmental and social institutions; Morse wrote 'Korean Interviews,' an anthropological overview of Korean social customs, which, for the most part, was anonymously based on his conversations with Yu.

With Japan's victories in the Sino-Japanese War (1894–95) and the Russo-Japanese War (1904–05), the establishment of a Japanese protectorate in Korea in 1905, and the Japanese annexation of Korea in 1910, the balance of these intellectual formations shifted. One US anthropologist, Frederick Starr,

continued to do research in Korea during the Japanese colonial period, making six research trips from 1911 to 1930. But the combination of Starr's sparse publication on Korea and his marginality in the discipline ensured that this work was poorly known, then and since. Instead, under colonial conditions, Japanese anthropology and related disciplines such as archaeology and folklore became dominant in the institutionalized study of Korean society and culture; prominent Japanese scholars of Korea included Torii Ryūzō, Sekino Tadashi, Imamura Tomo, Murayama Chijun, Zensho Eisuke, and Akiba Takashi. Some of this research took place under the auspices of the colonial Government General of Chōsen or other allied organs and was at least nominally oriented to the problems of colonial governance. Much also played into thematic poles of colonial ideology, emphasizing either the difference of Koreans from Japanese in more or less essentialized terms, or the ostensible common ethnoracial origins of Koreans and Japanese and thus the supposed preservation in Korea of traces of a more primordial Japan, with the latter relatively pronounced given the assimilationist design of much Japanese colonial policy in the peninsula. For these reasons, post-1945 critiques of colonial knowledge in the Koreas, the earliest of which significantly preceded the rise of postcolonial and post-Orientalist critique in Anglo-American anthropology, have sometimes offered blanket repudiations of this Japanese scholarship. Even as this has been the case, however, some research foci, conceptual frameworks, and findings of colonial anthropology have carried forward into subsequent social and cultural analysis of the Koreas. Akiba, for instance, gave impetus to later work on Korean shamanism, which he portrayed as located within a distinct female cultural sphere opposed to the Confucian sphere of men. The topic of shamanism, the problematic of gendered spheres, and the revision of this problem remained important to much village-based ethnography from the 1940s to the 1980s (Pai, 2000; Atkins, 2010: 52–101).

As in the late nineteenth century, Japanese and other foreign anthropological research during the colonial era coexisted with Korean scholarship on national folklore and cultural history. Much of this Korean scholarship in turn bore connections to the broader intellectual movement of cultural nationalism, which gained strength in the colonial milieu from the beginning of the 1920s. Of the four folklorists whom Roger L. Janelli (1986) regards as central, Yi Nŭnghwa and Ch'oe Namsŏn undertook mostly philological research. Both treated shamanism as deeply imbedded in Korea's history and culture and as a locus of its indigenous worldview, and Ch'oe in particular sought linkages for this and other elements in the Asian mainland, thus displacing colonial claims of a primordial Japanese–Korean racial and cultural unity. Son Chint'ae and Song Sŏkha, meanwhile, undertook fieldwork to examine aspects of Korea's folk culture; the former understood this in Tylorian fashion as suffused with survivals from the national past while the latter, more pragmatically and romantically, sought its preservation against encroaching change.

Divided Korea and Village Ethnographies

The end of Japanese colonialism in 1945 was followed quickly by separate occupations of the south and north of Korea by the United States and Soviet Union, respectively. Great power sponsorship of ideologically compliant regimes hardened these separate zones of occupation into competing states by 1948, while the accelerant it poured onto Korean social divisions set the stage for the outbreak of full-scale fighting in the Korean War of 1950–53. The political economy of sociocultural research in both halves of the divided nation was interwoven with these changes. In the south, Song Sŏkha and Son Chint'ae continued as central figures, and the predecessor organization to the Korean Anthropological Association, a museum of Korean folklore and anthropology, and the first academic department of anthropology were all established by 1946 (Chun, 1999: 125–160). Meanwhile, US anthropological researchers Cornelius Osgood and Eugene Knez conducted or began their village-based ethnography under the auspices of the US occupation government. During the Korean War itself, military-sponsored team anthropological research on the effects of temporary North Korean occupation of southern villages, along with refugee research, was among the techniques used to attempt to understand the 'Sovietization' of North Korean society itself. Notwithstanding the framing of this wartime research by conceptually blinkered Cold War tropes, and the apparent assumption of a monolithic 'culture of communism,' it actually found complex interactions between existing village social processes and real or ostensible political commitments, and in many respects was of a piece with the peacetime political and social anthropology of villages that would follow. For decades after the occupation, the United States would remain the major training site for perhaps most South Korean researchers, and the traditions have had strong ties as a result, though Japanese research on South Korea has also continued. Simultaneously, in North Korea, anthropology has had a role as a contributor to the intellectual project of socialist modernity, but the precise nature of that role, as well as the character of the connections of this research practice to other socialist anthropologies, remains a topic of ongoing investigation.

At the risk of overgeneralization, it can be said that the classic anthropology of South Korean village life that was predominant from the 1950s through approximately the mid-1980s had a sociological emphasis that distinguished it from other adjacent anthropologies. Village organization, its relation with structures and practices of kinship, and religion were among its major topics. Even in the last case, however, the tendency to abstract out religion or culture as an autonomous system was little in evidence, certainly in comparison to the postwar anthropology of Japan, for which the influence of the culture and personality school and its apotheosis in the work of Ruth Benedict's *The Chrysanthemum and the Sword* was important. The first English-language ethnography of Korea published in this period, Osgood's *The Koreans and Their Culture* of 1951, was also internally heterogeneous; the author appended to his village study a historical account of Korea from ancient times, out of a conviction that such information was lacking and thus necessary background for his readership.

Some specific topics of this era, such as the prevalent clan/lineage structures present within villages and their relation to village sociopolitical authority, were more pronounced in Korean-language work (e.g., Kim, 1979). But there were also several crosscutting common issues. In the last edition of this encyclopedia, Nancy Abelmann wrote of a set of

dichotomies that tended to structure Korean village studies, whether sustained or contested in various ways. These were between elite and non-elite culture and practice, between Confucianism and shamanism, and between male and female. One of the strongest conceptual developments of these dichotomies (and others) occurred in the work of Vincent S.R. Brandt (1971). Confronting an unexpected diversity of villagers' orientations toward kinship and community, and following perhaps most closely the model of models in Edmund Leach's *Political Systems of Highland Burma*, Brandt postulated the existence of dual, hierarchical and egalitarian cognitive ethical structures differently expressed in different situations. With the general anthropological turn toward practice and performance, and a specific interest in ritual, ethnographies of South Korea called into question the cleanliness of these dichotomies as either cognitive map or social actuality. In the early writings of Roger L. Janelli and Dawnhee Yim Janelli (1982) and Laurel Kendall (1985), it was in a sense deceased ancestors who served as the vehicles for this complexification, insofar as they are the common focus of much Confucian and shamanic ritual practice. Kendall, especially, was specifically concerned to question the notion of a separate 'women's sphere' of Korean religious and ritual activity.

There were, of course, works that fell outside this set of issues. In a more materialist direction, some research examined the transformations of objects of everyday life that was an aspect of the 'modernization' of villages. With a more explicitly critical attitude toward 'modernization' as a concept, Clark Sorensen (1988) related village changes to the larger political economy of industrialization and urbanization and the energetics of peasant households. Meanwhile, tracking more toward French structuralism, though also deeply rooted in classical Korean sources, Kang Shin-pyo explored the possibility of a distinctive Korean cultural grammar; he also offered an early, critical, cultural examination of the rhetoric and experience of high-speed development in South Korea (Kang, 1986).

Recent Trends

Between roughly the mid-1980s and the early 1990s, the anthropology of South Korea underwent a shifting of its sites away from a village focus in dialogue with changes in the discipline and in Korean society. The rise of discourse-based approaches within anthropology encouraged attentiveness to the imagination of tradition, culture, and nation. Simultaneously, within South Korea, movements of students, laborers, farmers, urban squatters, and others opposed to the ruling authoritarian regime and the political economy it supported grew in strength, rooting themselves ideologically in an acutely critical historical and cultural consciousness. Some ethnography was directly concerned with these movement formations. Seung-Kyung Kim's (1997) examination of female workers and labor mobilization in an export-processing zone was focused also on the dynamic tension between gender ideologies and new worker identities. Nancy Abelmann's (1996) study of an agrarian and student movement was permeated with activists' own understanding of their historicity, much of which revolved around the praxiological category of the *minjung*, very approximately the 'folk' or 'common people.' Even in anthropological writing on other topics, however, self-conscious attention to the construction and politics of culture suffusing anthropology and Korean public discussion was evident. Roger Janelli's ethnography with Dawnhee Yim Janelli (1993) of a South Korean corporation was cast against deterministic understandings of the relations between culture and capitalism, even as it tracked also the deployments of notions of familial and village culture by the firm's managers and employees. Laurel Kendall's (1996) account of marriage and wedding practices treated them as an arena in which conceptions of tradition and modernity are negotiated. Further work on shamanism in this period, by Kendall, Kim Kwang-Ok, and others, examined its increasing use as a social and political symbol, as well as the social relations of spokespersonship and marginalization entailed in that appropriation.

Since the 1990s, the international anthropology of the Koreas has continued its diversification of topics. Over roughly the same period, anthropology as practiced in South Korea itself has become thoroughly international in its research scope. No longer is Korean society its almost sole focus, though of course domestic research remains significant. These factors, combined with the large number of new scholars entering the field, make a complete overview impossible. What follows should thus be read as simply an identification of some important recent and contemporary research directions.

Much ethnography of the past two decades has tracked the shifting fortunes of South Korea's economy and the policies and practices of social governance with which it is intertwined. From the early 1990s, Korean anthropologists devoted attention to the apartment-based lifestyles, status consciousness and stratagems, educational focus, and transformed family and gender relations of the new urban middle class, and from around the turn of the millennium anthropologists based abroad have followed suit. Laurel Kendall's (2009) most recent work on shamans includes examination of the intersection of the world of spirits with the animating forces of consumptive capitalist desire. In a good deal of this research, the whiplash of the recalibration of narratives of self and nation in concert with the vertiginous ups and downs of the economy, particularly with the Asian financial crisis of the late 1990s, is front and center. In Laura Nelson's (2000) ethnography, middle class consumption and the gendered moral panic about (over)consumption are considered together. The supposed excessive spending habits of young female consumers, enamored with foreign goods, becomes the anchor for a discourse about the loss of national common purpose. Nancy Abelmann (2003) treats the melodramatic turns and keywords that stretch between South Korean media and women's life stories of rapid transformation. The consequences of the financial crisis included a state embrace of neoliberalism, manifest in new discourses of the self-cultivating individual and shifts in a host of labor and social welfare policies. These are familiar aspects of neoliberalism as a global governmental technology, but Jesook Song (2009), focusing centrally on initiatives concerned with homelessness, highlights the retrenchment of conservative familialist ideology with which they were connected in the South Korean case.

Other research has examined South Korea's increasingly multifarious variety of transnational articulations over the past several decades. Examinations of multiple diasporic communities with links to both Koreas have been a forerunner of this trend; in Korean studies, the tendency to highlight such historical and ongoing connections has been pronounced and long-standing. Recent work has turned to specific, mediated forms of Korean outmigration. Eleana J. Kim (2010), for instance, has focused on the transnational adoption complex, which facilitated the movement overseas of large numbers of South Korean children over a course of decades. Kim's work weaves the social, ideological, and bureaucratic production of this form of adoption together with its political location and intimate effects among South Koreans and adoptees abroad. Other studies have begun to examine the strategic practice and affective work of families that split, often for long periods, in order to secure their children access to education in other countries while one spouse remains employed in South Korea. Meanwhile, in South Korea itself, socioeconomic shifts since around 1990 have led to an influx of two major classes of migrants: labor sojourners, increasingly employed in South Korean manufacturing, construction, and other industries, and foreign brides, recruited in response to a perceived national crisis of familial reproduction, particularly in rural regions. Both are the subject of a good deal of emerging research. At the interstices of these movements, Caren Freeman (2011) examines the case of ethnically Korean Chinese migrants who strategically deploy and manipulate kinship in efforts to stabilize their residence in South Korea. Other anthropologists and sociologists have considered the discourse and actuality of 'multiculturalism' (*tamunhwa*), simultaneously highly structured by gender, that has arisen in the wake of these phenomena within South Korean society, long ideologically constructed as monoethnic and monocultural. Still another focus of recent work is on the transnational imaginaries engendered by various instances of Korean participation in global events or by the circulation of Korean products in foreign settings. Transnational sport is one important topic (e.g., Joo, 2012), while anthropological and sociological considerations of the 'Korean Wave' (*Hallyu*) – the new popularity of South Korean media abroad – have examined its reception and localization in a variety of international settings as well as the contested understanding of its significance in the country of its origin.

The past in South Korea is rarely really past, and from the 1990s onward the traumatic pasts of the twentieth century have increasingly been opened to public discussion with a loosening of authoritarian-era restrictions on speech and publication, a process that reached a momentary apex in the 2000s with the troubled efforts of a national Truth and Reconciliation Commission. Anthropologists have turned an eye to the historical, memorial, and cultural politics of these processes. One of the first to do so was Seong Nae Kim (1989), who considered the return of the repressed April Third Cheju Uprising and massacres of 1948 in shamans' rituals and other locations. Other studies have examined the legacies of violence and the local politics of division in villages torn apart during the Korean War, or the fraught and contested memories of other traumatic historical events, such as the 1980 Kwangju Uprising. More recently, C. Sarah Soh's (2008) work on the 'comfort women' – the institution of wartime sexual slavery in the Japanese empire – contextualizes the phenomenon both in terms of its appropriations by various postcolonial states and activist groups and in relation to longer histories of mobilized public sexuality. Other approaches to the presence of history in contemporary processes draw inspiration rather from considerations of the rendering of history and culture as national heritage, and the selectivity of narratives of the national past fostered by Korean states and a variety of other actors. Moreover, with the return of local self-government at the beginning of the 1990s and new imperatives for regions and municipalities to compete for tourism and development projects, local heritage in South Korea began to draw increased attention. Scholars have examined the intersection of local heritage with national and local electoral politics, its commodification for tourism, and its entanglements with technical disputes (e.g., Kim, 1996; Oppenheim, 2008). Tying together these trends are new attempts to write deep histories of regional communities, historical consciousness, and place-making across long spans of time, exemplified by a collective examination of the Sŏsan region by a team of Korean anthropologists and by a variety of interdisciplinary projects on local areas often rooted in regional South Korean universities.

Recent research on Korean division, and on North Korea, has built on past trends while also embarking in new directions. Work of the late 1990s emphasized the imagination of the North in the South, including various idealizations of North Korean life and authenticity fostered in the absence of much actual contact. Since that time, against the backdrop of a variety of political shifts, such contact between North and South Koreans has increased greatly. Temporary reunions of families originally divided by the Korean War accelerated for a period after 2000 and have drawn additional attention since then. Other studies have examined North Korean refugees, following both their movement through China and other areas and the resettlement of some in the South. Insofar as North Koreans newly resident in South Korea both claim and are imputed with Korean identity while simultaneously experiencing displacement and discrimination, they also pry open the question of the heterogeneity of Koreanness. This research thus bears articulations with the other examinations of migration and multiculturalism noted above. At the same time, however, some scholars have attempted to shine new anthropological (if not ethnographically based) light on the ideological organization of North Korean leadership, state, and society. Sonia Ryang (2012), with an explicit goal of humanizing North Koreans against a tide of portrayals that do the opposite, uses North Korean literature to consider the transactional relationship between individual selfhood and the sovereignty of the Great Leader. The abstract infinitude of the Great Leader's love in these writings demands continual acts of love and sacrifice on the part of his subjects. Viewed as political theology, the idolization of Kim Il Sung (and in differing ways, of his successors) ceases to be *sui generis*, sharing, for example, structural similarities to some Christian understandings of the love of God. Heonik Kwon and Byung-Ho Chung (2012) pursue similar deexoticizing goals along a different pathway. For them, what is basic to the North Korean political system and the rule of the Kims is Weberian

charismatic authority; what needs explanation is its persistence and routinization. In analyzing this, the authors draw on Clifford Geertz's classic examination of the 'theater state' as a useful basis for understanding contemporary North Korea.

In only the past decade, anthropological work on the Koreas has proliferated greatly in quantity and variety. It shows every sign of continuing to do so. Some emerging scholarship takes old issues in new directions, examining shamanism through the lens of the commodification of fortune telling, for example, or social movement practice through the question of new millennium movements' commitment to pragmatism, to the ideology of no ideology. Other topics are relatively new for the field. Anthropologies of media use and reception follow on the intense interest in film within South Korea, and the growing significance of internet communities and digital media in its social life and politics. Research is being done on advertising as a cultural process, and on 'national branding' by organs of a state very explicitly and self-consciously concerned with building its 'soft power.' The anthropology of science, and science and technology studies more generally, has an expanding place in Korean studies – with examinations of biotechnology perhaps especially prominent in the wake of the Hwang Woo-suk cloning scandal. Linguistic anthropology, long a somewhat peripheral subfield, is increasingly in dialogue with sociocultural research. If there remains, in some circles, the perception that anthropological work on the Koreas stands apart from the discipline as a whole, immersed in its own distinctive concerns, that perception has become somewhat distant from reality.

Asia, Sociocultural Overviews: South Asia

Andre Beteille, Delhi School of Economics, University of Delhi, Delhi, India

Published by Elsevier Ltd.

Abstract

'South Asia' stands for seven countries: India, Pakistan, Bangladesh, Nepal, Bhutan, Sri Lanka, and the Maldives. The article discusses the overall features of Indian civilization, religion, and language; sociocultural diversity including collective identities of caste and tribe, village organization, family, and kinship; and the important recent changes in Indian society resulting from globalization and related factors.

Area and Population

The term 'South Asia' has come to stand for a group of seven countries: India, Pakistan, Bangladesh, Nepal, Bhutan, Sri Lanka, and the Maldives; and it is in that sense that it will be used in this article. These countries differ greatly in area and population, and in geographical aspect and location. India, with over a billion inhabitants, has the second largest population in the world; the Maldives have a population of only a few hundred thousand people. Nepal and Bhutan are entirely landlocked; Sri Lanka is an island in the Indian Ocean; and the Maldives comprise a chain of more than 1000 islands, most of them uninhabited.

The people of these countries have a shared past by which many of their present social and cultural characteristics have been shaped. Demographically, economically, and politically, India, Pakistan, and Bangladesh are the three most important countries of the region. Until 1947, they were one country. It was partitioned in the same year, when India and Pakistan became separate and independent nations. Pakistan was in turn partitioned in 1971, leading to the creation of Bangladesh as a separate country. The first partition was occasioned by differences of religion, and the second by differences of language. In each case the partition was attended by considerable movements of population.

The Indian subcontinent, comprising India, Pakistan, and Bangladesh, was under British rule for a long time, as was also Sri Lanka. The two landlocked kingdoms of Nepal and Bhutan never came directly under British rule and remained relatively isolated from the economic and political forces released by it. Although many social and cultural changes have taken place in the region since the end of colonial rule in the middle of the twentieth century, large parts of it still remain economically backward.

The subcontinent is the home of a very ancient and distinct civilization that may be described as the 'pan-Indian' or the 'Indic' civilization. This civilization had its origin in the Indo-Gangetic plain in the second millennium BC, and it antedates the birth of both Christianity and Islam. Its characteristic bearers today are the Hindus. It has undergone many changes, and its influence has not only permeated throughout India and its neighboring countries, but also extended to lands beyond the seas such as Indonesia, Cambodia, and Thailand. India is not only the home of Hinduism, it also gave birth to Buddhism, which is the official religion of Bhutan and the predominant religion of Sri Lanka.

Religion and Language

Although Hinduism has had the longest and most pervasive influence on society and culture in the subcontinent, Islam too has a strong presence in it, including present-day India. Pakistan is an Islamic country; Bangladesh has a predominantly Muslim population; and although the Muslims are a minority in India, they are a very large minority. The medieval phase of Indian history was dominated by Muslim sultanates and empires; and the Muslim population of Bangladesh, Pakistan, and India taken together make up a considerable part of the Muslim population of the world as a whole.

In South Asia, the divisions of religion cut across those of state and nation, and the region as a whole may be viewed as a mosaic of religious communities, sects, and denominations. India provides an extreme example of coexistence of diverse religious faiths and practices. Although the Hindus predominate in the country as a whole, there are districts in which Sikhs, Muslims, or Christians predominate. Again, Nepal is a predominantly Hindu country, but there are areas in which Buddhists predominate; in Sri Lanka it is the other way around.

South Asia is the home not only of many religions but also of innumerable languages, and, whether on the plane of cultural values or of social identity, language is as important as religion. Like the divisions of religion, those of language also cut across the boundaries of state and nation. The Punjabi-speaking community is divided between India and Pakistan; the Bengali-speaking community between India and Bangladesh; and the Tamil-speaking community between India and Sri Lanka. Sometimes, as in Sri Lanka, where the Sinhala-speakers are predominantly Buddhist and the Tamil-speakers predominantly Hindu, the divisions of language and religion follow the same line. But this is not always the case. It is common in the subcontinent, if not characteristic, for the divisions of language and religion to cut across each other; there are Muslims, Hindus, and Sikhs among the Punjabi-speakers in India and Pakistan, and Hindus and Muslims among the Bengali-speakers in India and Bangladesh.

Because of historical and demographic reasons India has the largest variety of languages among South Asian countries: it is indeed the most polyglot country in the world. There are more

 http://dx.doi.org/10.1016/B978-0-08-097086-8.12019-7

than a dozen literary languages, divided between the Indo-Aryan and the Dravidian families of language. In addition, there are numerous tribal languages and dialects belonging to the Austro-Asiatic, the Tibeto-Burman, and other families. In India, as in the subcontinent generally, the divisions of language correspond more closely to geographical divisions than do the divisions of religion; but here too, population movements through the centuries have led to a certain dispersal of language communities.

If the civilization of South Asia had a design, it was most clearly visible in the Indian subcontinent until its first partition in 1947. Visitors to the area from far and near have been for centuries struck by the distinctness and continuity of that design, and have commented on its influence on society and culture in the different countries of the region. Despite the changes and upheavals of the twentieth century, its distinctive features are still visible, not only in India, but elsewhere as well.

Accommodation of Diversity

A brief sketch of the design of the traditional civilization of the subcontinent will be provided as an aid to the understanding of the multitude of beliefs, practices, habits, customs, and manners prevalent in the region to this day. The first striking feature of this design is the accommodation of diversity. The rich, ethnographic record available from the middle of the nineteenth century onward shows an endless, almost inexhaustible, variety in material culture, social arrangements, and religious beliefs and practices. Some of the variation in material traits, in matters such as food, dress, and habitation, may be explained by variations in geographical environment and natural resources. But the cultural variation is far in excess of what would be required by variations of natural environment. For instance, even where its basic ingredients are the same, food might be prepared and served differently among the different castes and communities in the same village.

Then there is the great diversity of social arrangements in matters relating to family, marriage, descent, inheritance, residence, and so on. What needs to be stressed is not simply the diversity of practices, but also the diversity of rules; they were the despair of the colonial administrators of the nineteenth century who sought to codify the laws and customs of the subcontinent. There is finally the profusion of religious beliefs, doctrines, rituals, customs, and usages, which have been mentioned.

The presence of diversity has been more than a matter of mere existence. In Indian society in particular and South Asian societies in general, it has been sustained by law, custom, and popular religion. Accommodation without assimilation has been a core value of Indian civilization until modern times. It has led to the coexistence of a large multiplicity of beliefs and practices as well as of social groups. Adding new components has not meant discarding old ones, and new and old components of the most heterogeneous kinds have existed cheek-by-jowl to a greater extent than in other civilizations. The Indian subcontinent has been and still largely remains a vast mosaic of tribes, clans, castes, sects, and communities, each with its own identity.

Collective Identities

The second distinctive feature of South Asian societies is the predominance of collective identities. In the past, what counted was not so much the individual but the group of which he was a member by birth, and this continues to a large extent even now. It has often been said that traditional Indian society was a society not of individuals but of castes and communities. As has been noted, there was a great multiplicity of groups, and this multiplicity was a feature even of small local communities. The members of a single village might observe different religious practices, speak more than one language, and belong to a dozen or more different castes and subcastes.

Collective identities were maintained by fidelity to the customs of one's ancestors and by rules for the regulation of marriage. In course of time, subtle differences developed in craft practices, dress, and ornamentation, marriage rules and ritual observances between groups having the same origin. Each group and subgroup maintained its distinctive style of life and transmitted it from generation to generation. The group preserved a sense of its own identity despite changes in its social position. The high value placed on the accommodation of diversity allowed and indeed encouraged each group to retain a strong sense of its own identity.

The persistence of collective identities may be illustrated with two examples from the subcontinent. The first relates to what has been called 'the Hindu method of tribal absorption.' In the past, tribal groups, which were relatively isolated from the wider society sometimes established relations with that society, discarding some old practices and acquiring some new ones. In this way, a tribe was often transformed into a caste but, despite a change of name and to some extent also of social position, it preserved its old collective identity. The second example relates to the survival of caste identities despite changes of religion. The census reports of British India show that in the Punjab, on both sides of the present international frontier, the same castes, such as Ahir, Jat, and Gujjar were present among Hindus, Muslims, and Sikhs. When a section of a Hindu caste embraced Islam or Sikhism, it adopted a new religion but did not abandon its old and distinct collective identity.

Hierarchical Organization

The accommodation of diversity did not mean that the tribes, clans, castes, sects, and communities that were allowed or even encouraged to maintain their distinctive identities were all placed on the same plane of equality. Diversity was organized on the basis of hierarchy and not of equality, and that is the third distinctive feature of the traditional civilization of South Asia. It is true that all communities were allowed or even encouraged to maintain their distinctive styles of life; but they were not all equally esteemed. While all premodern civilizations were hierarchical to a greater or lesser extent, the principle and practice of hierarchy were carried furthest on the Indian subcontinent, particularly among the Hindus.

Hierarchy is not simply a matter of inequality in the distribution of material resources or of life chances; it is above all a system of values according to which the division of the

world into social groups deemed to be of unequal worth is a part of the natural scheme of things. The hierarchical conception of society found its fullest expression in the classical Hindu texts known as the *Dharmashastra*, which provided the framework for Hindu law. Although the law has changed radically in the direction of equality, the bias of custom is still often in favor of hierarchy.

The Hindu caste system has been represented as the prototype of a hierarchical social order. But hierarchy extends beyond caste and permeates social relations and social institutions of the most diverse kinds among Hindus, Muslims, Buddhists, and others throughout the region. Despite the doctrine of equality characteristic of Islam, agrarian relations and gender relations are cast in a deeply hierarchical mold in Pakistan and to some extent also in Bangladesh.

The Village

Colonial administrators throughout the nineteenth century saw the subcontinent as essentially a land of villages. They have left behind memorable accounts of the unity, the self-sufficiency, and the continuity of the Indian village. A large number of village studies have been conducted in India by professional anthropologists and others since the country became independent in 1947. Similar studies have been conducted in Sri Lanka, Pakistan, Bangladesh, and Nepal. In the paragraphs below there follows a brief account of the broad social characteristics of the Indian village, many of which may also be found in villages in the other countries just mentioned.

In the past, the Indian village had a distinct physical identity, which became particularly prominent during floods, famines, and other natural calamities. Most villages were nucleated, although there were also dispersed villages, depending in part on the terrain. The life of the village was based on an economy of land and grain, and its rhythm was, and to a large extent still is, governed by the annual cycle of agricultural activities. The village also has an annual cycle of religious ceremonies and festivals, and the two cycles are related closely. With the development of transport and communication in the twentieth century, and particularly since the 1950s, the isolation of the village is becoming progressively reduced, although not at the same pace in all parts of the country or the region. The less-isolated villages are now becoming urbanized, though in a highly uneven manner.

The social morphology of the village shows considerable variation in terms of size and internal differentiation. Irrigated villages in river valleys and close to the ancient and medieval centers of civilization tend to have an elaborate structure; 'dry' villages in the remote areas tend to be smaller and simpler in their structure. Only the latter may be described as communities of peasants. The former are often highly differentiated and stratified. They include noncultivating landowners, owner–cultivators, cultivating tenants, sharecroppers, and agricultural laborers, in addition to groups of families associated with various specialized crafts and services, usually on a hereditary or quasi-hereditary basis. Agrarian reform and the expansion of the market are changing some of this, although many of the older features remain.

Its relative isolation and self-sufficiency and its well-knit division of labor between agriculture, crafts, and services gave the Indian village a certain unity. In the nineteenth century – and even later – it was often described as a 'little republic.' But it was not a republic of equals. In the larger irrigated villages the social boundaries between the superior, intermediate, and inferior sections of the community – landowners, tenants, agricultural laborers, priests, potters, and scavengers – were clearly maintained. If there was a certain unity in such villages, as indeed there was, it is best described as a 'vertical unity.' The unity of the village has been weakened in recent decades, but that does not mean that the inequalities have all disappeared.

While it is true that South Asia is a land of villages, one cannot ignore the presence of towns and cities in it. The subcontinent has cities going back to ancient and medieval times, and India had urban centers before most of Europe did. In the past, towns and cities grew around places of worship, the courts of kings and princes, and commercial and trading centers. Colonial rule led to the creation of a new kind of city, mainly along the coast, such as Calcutta, Madras, Colombo, Bombay, and Karachi. In the years since the end of colonial rule, industrialization has added to the population of existing cities and led to the creation of new ones. The urban middle class and the industrial working class are important factors in the economic and political life of contemporary India.

Returning briefly to the Indian village, a prominent place was occupied in it by caste. Indeed, caste may be viewed as the social basis of the division of labor in it, and the differentiation and stratification in the Indian village cannot be understood without taking caste into account.

Caste

Caste is an institution of great antiquity, and it has shown resilience in the face of the economic and political changes of the twentieth century. In its origin and fullest development, it is an institution of the Hindus, but near analogs of the Hindu caste system may be found among Sikhs, Muslims, and Christians on the subcontinent and among Buddhists in Sri Lanka; and it is of course very important in the predominantly Hindu population of Nepal. On the doctrinal plane, Hinduism, Buddhism, and Islam are different from each other; on the plane of everyday life at the local level, social divisions among Hindus, Muslims, and Buddhists act in broadly similar ways in most parts of South Asia.

The caste, the subcaste, and even the subsubcaste, to each of which the term *jati* may be applied, maintained its identity and continuity through the regulation of marriage. The most general rule was the rule of endogamy, and among Hindus this was supplemented by the rule of hypergamy. In the past, Hindu law prohibited intercaste marriage except under very, specific conditions; the law has now changed, but the bias of custom is still in favor of endogamy among the Hindus, and to some extent also among the others.

Every caste or *jati* was in principle associated with a specific occupation, although agriculture was open to most if not all castes. The association between caste and occupation was stronger among the Hindus than among the others, but from

the end of the nineteenth century, it began to weaken even among the former. A very important factor behind the weakening of the association has been the emergence, since the middle of the nineteenth century, of a large and increasing number of occupations that are 'caste-free' in the sense that they have grown outside the framework of the old division of labor based on caste.

The different castes are socially ranked; indeed, it is in the caste system that the principle of social ranking finds its most extreme and elaborate expression. In South Asia, castes are ranked among all religious groups, but the ranking is not as rigid or as exhaustive among the non-Hindus, as it is among the Hindus. Caste ranking among the Hindus was expressed in the idiom of purity and pollution, but that idiom is now less pervasive than before, and new criteria of social ranking, having little to do with caste in the traditional sense, are becoming increasingly salient, particularly in the urban areas.

Family, Kinship, and Marriage

Given the great significance of the rules regulating marriage and in particular the rule of endogamy, it is not surprising that there is a close association between caste and kinship. Through repeated intermarriage from generation to generation, all the members of the local section of a caste or subcaste become related to each other by real or putative ties of kinship. This is generally true of all the major religious and linguistic divisions of South Asian society.

Much has been written about the prevalence of the joint family in the subcontinent and the changes it is undergoing as a result of urbanization, industrialization, and modernization. The Hindu undivided family had certain legal characteristics peculiar to itself, and some of these are still recognized by the law in India. One important feature of the family in the subcontinent, whether among Hindus, Sikhs, Muslims, or Christians, is that marriages are still to a large extent arranged by parents and older relatives, and the new couple generally lives in the parental home immediately after marriage, even though it may set up a separate household after one or more children are born.

Reference has already been made to wide variations in the rules of descent, inheritance, and marriage across the many and diverse communities that inhabit the region. But through all these variations, kinship has a significant place in social life everywhere and among all communities. Relatives are numerous and various, and the obligations of kinship are cherished and cannot be denied easily. The rules of endogamy act against the formation of real ties of kinship between members of different castes; but they do not prevent the formation of fictive ties of kinship between them. The idiom of kinship is used extensively in interpersonal relations across castes and communities in villages throughout the region.

Changes are undoubtedly taking place in the size and composition of the household, particularly in the rapidly growing cities. But even where nuclear households outnumber extended ones, the matrix of kinship within which they operate gives them a different character from their counterparts in the West. The boundaries between households are porous, and no household is secure against intrusion by cousins, uncles, aunts, nephews, nieces, and grandparents.

In discussing caste, kinship, and family it is impossible to ignore the subject of gender, although only a passing reference to it is possible here. Despite variations according to language, religion, and caste, and between patrilineal and matrilineal communities, women have since time immemorial occupied a subordinate position in South Asian societies. Polygamy was sanctioned by law among both Hindus and Muslims. In India, it is now prohibited by law among Hindus but not among Muslims; it is permitted by law in Pakistan, and attempts to regulate polygamy by law have had little success among Muslims. The position of women is changing in all countries and among all communities in South Asia, although the change is highly uneven. Here, more important than the variations of language, religion and caste are those that arise from education, occupation, and income.

New Institutions and Classes

The first impediment against attempting a concise account of society and culture in South Asia arises from the problem of variation; the second impediment arises from the problem of change. Two important developments in the subcontinent since the middle of the nineteenth century have to be noted. These are, first, the growth of open and secular institutions such as schools, colleges, universities, libraries, laboratories, hospitals, law courts, and newspapers; and, second, the emergence of a new middle class based on a new educational system and a new occupational system. These two related developments have taken place everywhere, but most conspicuously in India where they are now a significant feature of the social and cultural landscape.

Open and secular institutions are sustained by norms and values that are very different from the norms and values by which the traditional institutions of South Asian societies have been sustained. The new institutions are often at odds with the old ones, which exert various kinds of pressures on them and sometimes threaten their very survival. At the same time, and particularly in a country like India, they have grown to an extent that makes it difficult to dispense with them or to devise alternatives to them that are fully in harmony with the institutions of the past. As a result, the conflict of norms and values has become endemic in these societies.

The new middle class is both the creation and the creator of the open and secular institutions just referred to. The origins of the Indian middle class go back to the first half of the nineteenth century. Its first beginnings took place in the presidency capitals of Calcutta, Bombay, and Madras in each of which a new university was established in 1857. The graduates of these universities and of the others which came up in course of time became administrators, managers, lawyers, doctors, scientists, teachers, and clerks. The Indian middle class is now very large, at well over 100 million persons. Although it is still a relatively small proportion of the population of the country, it is among the largest and the most differentiated of the middle classes in the world.

The emergence of a new and increasingly dynamic middle class has not led to the effacement of the old identities and

distinctions based on language, religion, and caste. Those still remain, although they are now coming to be organized in a different way. The middle class in turn is differentiated not only in terms of occupation, income, and education, but also in terms of language, religion, and caste. Caste and class reinforce each other in some respects and cut across each other in others. While there is some individual mobility, it does not lead to the equal distribution of all castes and communities among the different economic strata. The social mosaic is, thus, becoming in some sense even more complex than in the past.

Media, Movements, and Modernity

Since the turn of the millennium, South Asia has rapidly appeared as a prominent region in a globalizing world. The Indian economy, during the decades after independence largely restricted by state control, has been liberalized and this has strongly influenced not only trade and industry, but also social and cultural aspects of society. A wide range of 'foreign' consumer goods are now available for those that can afford them, and members of an urban middle class are attracted by job opportunities in multinational companies or new domestic enterprises producing for the global market. Thus, the social and cultural environment of the middle class is not confined to postcolonial institutions in the South Asian social landscapes. The horizon of expectations, not least regarding matters of education and occupation, extends far outside the region.

This is of course a reality more accessible for wealthier sections of urban India – and particularly for people in cities which have emerged as hubs of the global Information Technology industry, such as Bangalore and Hyderabad – than for that vast majority of the population which is still outside this world of new possibilities. But also for the less fortunate, modern consumer goods, proper education, and successful occupational careers have become visions to struggle for. One reason for this is the enormous growth of mass media and other communication technologies through which images and knowledge of emergent life styles are disseminated.

Only a few decades ago, newspapers and television were media relevant mostly for a privileged, often English-speaking, middle class; while domestic film industries produced escapist entertainment for poor mass audiences. Today this cleavage has decreased. Daily newspapers and regional television channels are available in vernacular languages and popularized forms; simultaneously, the film industry in India – popularly known as Bollywood – is increasingly producing movies in order to attract the growing middle class and even a global audience, beside village India. The mobile phone has rapidly become a technical commodity in mass use.

While, in some sense, the cultural rift (between urban and rural, or modernity and tradition) within South Asia has diminished, social and economic differences have not. Much due to the influence of mass media, inequalities have rather become more visible and not least contested. Later decades has seen a rise of social movements and new political formations, which have changed the complexion of politics. In India, Hindu nationalism, low caste (*Dalit*) mobilization, environmentalism, anticorruption campaigns, and various regional movements have been on a steady rise, and at times agitations on specific issues have escalated in violence. Also this development could be interpreted as a sign of a how South Asia is transforming toward universal forms of norms and discourses. However, it could also be argued that certain traditional social and cultural aspects still prevail, for example the importance of family relations, religion, and the privileges of caste – even if in modified forms. Thus South Asia accommodates its own forms of hybrid modernities.

Assimilation of Immigrants

Rubén G Rumbaut, University of California, Irvine, CA, USA

Abstract

This article reviews the evolution of the concept of assimilation in American social science. It distinguishes *assimilation* from *accommodation* as modal adaptation outcomes of different immigrant generations, as well as various aspects that are commonly conflated by the concept (cultural adaptations, economic mobility, social acceptance into a native mainstream); discusses interrelated cultural (subtractive and additive acculturation), structural (primary and secondary integration), and psychological (identification) dimensions of the concept; and describes the process of 'segmented assimilation' – how it is that different groups, in varying contexts of reception and incorporation, adapt to and are absorbed into different sectors of the society.

"What happens 'when peoples meet'?" was the question with which Milton Gordon (1964: p. 60) opened his seminal chapter on "The Nature of Assimilation," referring to the "processes and results … of ethnic meetings in the modern world," which take place in a wide range of contexts from colonial conquest and military occupation to the displacement of indigenous peoples and to large-scale voluntary immigration. He identified seven 'variables' (or 'stages or subprocesses') of a complex 'assimilation process' to describe, in the American context, what happens to the 'sense of peoplehood' of ethnic groups, that is, of "groups defined by race, religion, and national origin, or some combination of these categories" (1964: pp. 27, 69–83).

International migrations produce profound social changes in both sending and receiving societies, in intergroup relations within receiving societies, and among the immigrants and their descendants. In varying contexts of reception, immigration is followed predictably not only by acculturative processes on the part of the immigrants, but also by varying degrees of acceptance, intolerance, or xenophobia about the alien newcomers on the part of the natives, which in turn shape the immigrants' own modes of adaptive response and sense of belonging. And immigration engenders ethnicity – collectivities who perceive themselves and are perceived by others to differ in language, religion, 'race,' national origin or ancestral homeland, cultural heritage, and memories of a shared historical past. Their modes of incorporation across generations may take a variety of forms – some leading to greater homogenization and solidarity within the society (or within segments of the society), others to greater ethnic differentiation and heterogeneity (Yinger, 1981, 1994; Massey and Sánchez, 2010). Those outcomes are shaped by the complex interaction of the (welcoming, neutral, or hostile) contexts of incorporation into which the immigrants are received by the society, and the resources and adaptations of the immigrants and their descendants (Portes and Rumbaut, 2014).

Assimilation is one such possible outcome. Sociologically, it has been defined as a multidimensional process of boundary reduction and brokering, which blurs or dissolves an ethnic distinction and the social and cultural differences and identities associated with it (Alba and Nee, 2003). At its hypothesized end point, formerly distinguishable ethnocultural groups become effectively blended into one. At the group level, assimilation may involve the absorption of one or more minority groups into the mainstream, or the merging of minority groups – e.g., second-generation West Indians 'becoming black Americans.' At the individual level, assimilation denotes the cumulative changes that make individuals of one ethnic group more *acculturated, integrated,* and *identified* with the members of another.

Ideologically, the term has been used in the past to justify selective state-imposed policies aimed at the eradication of minority cultures and the 'benevolent' conquest of other peoples. Two notorious examples are the campaigns, encouraged by the Dawes Act of 1887, to Americanize, Christianize, and 'civilize' American Indian children by removing them from their families and immediate environments and moving them into boarding schools like the Carlisle Indian School in Pennsylvania; and the 1898 'Benevolent Assimilation' policy of the United States to colonize and pacify the Philippines and quash its struggle for independence, pursuing an imperial interest under the guise of idealized purpose and beneficent intent (Miller, 1982). But the ideal of assimilation, more often tied to the metaphor of the 'melting pot,' has sought to dramatize, legitimize, and celebrate the consensual integration of immigrants and their descendants into a common national life – while ignoring the realities, inequalities, and potentialities of conflictual intergroup relations marked by enduring segregation, discrimination, marginalization, and exclusion.

In *Beyond the Melting Pot* (1963), their classic study of "the Negroes, Puerto Ricans, Jews, Italians, and Irish of New York City," Nathan Glazer and Daniel P. Moynihan concluded that the concept of assimilation could not elucidate the complex realities of the nation's largest city:

> To what does one assimilate in modern America? The 'American' in the abstract does not exist … The point about the melting pot is that it did not happen … The notion that the intense and unprecedented mixture of ethnic and religious groups in American life was soon to blend into a homogeneous end product has outlived its usefulness, and also its credibility. The persistent facts of ethnicity demand attention, understanding, and accommodation. (xcvii, 20, 290)

Evolution of the Concept

In academic and colloquial usage, in social science, public policy, and popular culture, the idea and the ideal of 'assimilation' have had a checkered history. A protean concept, over time the term has conflated various empirical descriptions and normative prescriptions to make sense of the incorporation of 'ethnic' difference in American life. The concept is used to refer at once to cultural adaptations, economic mobility, patterns of settlement and intermarriage, and social acceptance into a changing native mainstream. After more than a century of use and misuse, the term itself remains elusive, confusing, and contentious. For a 'canonical' concept, there remains surprising ambiguity as to its meaning, measurement, and applicability.

The earliest uses of 'immigrant assimilation' confirm the sociologist Robert Park's observation that it was a metaphor derived from physiology to describe, as in a process of digestion and absorption, how "alien peoples come to be incorporated … with a community or state" (1914: p. 611). As originally used, assimilation was a *transitive* verb, entailing the 'swallowing and digesting' (by the incorporating community or state, the subject of the action) of alien peoples (the object). Thus, a 19 May 1852 article in the newly founded *New York Times* observed that "The population of the United States is supplied by the world … Assimilation in America, thanks to a healthy and useful digestion, is equal to the largest supplies of aliment … Politically, the influx of life is only pernicious where the assimilative functions of labor and compensation are quiescent or disordered." A generation later, at the start of a new immigration from Southern and Eastern Europe, the *Times* editorialized on 15 May 1880, that "There is a limit to our powers of assimilation and when it is exceeded the country suffers from something very like indigestion … We know how stubbornly conservative of his dirt and ignorance is the average immigrant who settles in New York … these wretched beings change their abode, but not their habits in coming to New York." By 9 August 1903, another *Times* editorial noted that "Little more than one half of the people of the country at the opening of the twentieth century are of American parentage … Obviously the task of assimilation imposed on the American people is considerable." It was the 'American people' who did the assimilating; it was up to the 'Anglo-Saxon race' to absorb the foreigners.

In the twentieth century, 'assimilation' came increasingly, if almost imperceptibly, to be used as an *intransitive* verb. It was now the aliens who were the subject of the action of adapting and changing themselves *to* American cultural standards – 'acculturating,' as the process would later be called (Redfield et al., 1936) – and thereby embracing (or expected to embrace) a common national loyalty and identity. Already in Chicago in 1914, with immigration unabated and the large majority of its residents consisting of immigrants and their children, Robert Park (who saw the modern construction of national identities as entailing both the incorporative and acculturative modes of intergroup change) could write that:

> In America it has become proverbial that a Pole, Lithuanian, or Norwegian cannot be distinguished, in the second generation, from an American born of native parents … As a matter of fact, the ease and rapidity with which aliens, under existing conditions in the United States, have been able to assimilate themselves to the customs and manners of American life have enabled this country to swallow and digest every sort of normal human difference, except the purely external ones, like color of the skin.
>
> 1914: p. 608

'Americanization' became the synonym of assimilation – all the more during the national mobilizations for '100 percent Americanism' spurred by World War I, the Bolshevik Revolution, and their aftermath (Higham, 1955). Popular usage reflected the dominant currents of thought of the times. The sociological concept of 'assimilation' was honed during an era of rapid industrialization, urbanization, and a mass 'new immigration' from Southern and Eastern Europe in the late nineteenth and early twentieth centuries. So was American sociology, especially in Chicago, which became a natural laboratory for the study of the immigrant and the city. Grand narratives, such as Emile Durkheim's depiction of the shift from 'mechanical' to 'organic solidarity' in *The Division of Labor in Society* (1893), sought to grasp the transition from premodern folk to modern industrial society; they undergird the subsequent development of functionalist theories of modernization. Progressive reforms, rooted in a belief in the human ability to improve social conditions, especially with the aid of experts and rational efficiency, sought to grapple with the attendant problems of large-scale social integration. The teleological notion of an endlessly improving future and positivist assumptions of linear progress were made credible by the rapid expansion of science, technology, and economic innovation. The idea of progress came to dominate the worldview of the entire culture. The ideal of assimilation reflects that optimism in progress as a universal law.

Assimilation in American Sociology: Three Classic Formulations

The concept of assimilation seeks to grasp a contextual and not solely an individual reality that is complex, relational, and multidimensional. In what became arguably the most influential text ever published in the history of American sociology, Robert Park and Ernest Burgess gave the concept of assimilation its first classic definition: "a process of interpenetration and fusion in which persons and groups acquire the memories, sentiments, and attitudes of other persons and groups, and, by sharing their experience and history, are incorporated with them in a common cultural life" ([1921]1924: p. 735). They distinguished systematically between 'four great types of interaction' – competition, conflict, accommodation, and assimilation – which they related respectively to economic, political, social, and cultural institutions. *Competition* and *conflict* sharpen ethnic boundaries and the consciousness of intergroup difference. An *accommodation* (of a conflict or to a new situation) may take place quickly, and the person or group is typically a highly conscious protagonist of the process of accommodating those circumstances. In *assimilation*, by contrast, the changes are more subtle and the

process is typically unconscious, so that the person is incorporated into the common life of the group largely unaware of how it happened. Assimilation is thus very unlikely to occur among immigrants who arrive as adults. Instead, *accommodation* most closely reflects the modal adaptation of first-generation adult immigrants, while *assimilation* can become a modal outcome ultimately only for the malleable young and for the second and third generations, and then only if and when permitted by structural conditions of inclusion at the primary group level.

Assimilation thus defined takes place most rapidly and completely in primary (intimate and intense) social contacts, including intermarriage. *Accommodation* may be facilitated through secondary contacts, but they are too distant and remote to promote assimilation. Since the nature (especially the interpersonal intimacy, 'the great moral solvent') of the social contacts is what is decisive, it follows that 'a common language is indispensable for the most intimate associations of the members of the group,' and its absence is 'an insurmountable barrier to assimilation,' since it is through communication that gradual and unconscious changes of the attitudes and sentiments of the members of the group are produced.

But – crucially – language and acculturation alone cannot ensure assimilation if a group is categorically segregated, racially classified, and 'regarded as in some sense a stranger, a representative of an alien race.' That is why, Park emphasized in a later encyclopedia article (1930: p. 282), the English-speaking Protestant "Negro, during his three hundred years in this country, has not been assimilated … not because he has preserved in America a foreign culture and an alien tradition, for with the exception of the Indian … no man in America is so entirely native to the soil." Race and place (i.e., racial discrimination and residential segregation) become critical structural determinants of the degree of assimilation or dissimilation precisely insofar as they delimit possible forms of primary social contact and heighten social contrasts and conflict. To be considered assimilated, it is not enough to acquire "the language and social ritual of the native community" – i.e., to be acculturated – but also to be able to "participate, without encountering prejudice, in the common life, economic and political" (1930: p. 281). A century later, much the same could be said of millions of highly acculturated undocumented immigrants from Mexico, Central America, and elsewhere who are nonetheless excluded from the legal labor market and subject to systematic state persecution and unprecedented levels of deportations (Kanstroom, 2007; Ngai, 2005).

The 'melting pot' metaphor had been dismissed by Park and Burgess as a "'magic crucible' notion of assimilation" where "the ideal of assimilation was conceived to be that of feeling, thinking, and acting alike" (1924: p. 735). The end result of assimilation is not 'like-mindedness,' but rather "a unity of experience and orientation, out of which may develop a community of purpose and action … The extent and importance of the kind of homogeneity and 'like-mindedness' that individuals of the same nationality exhibit has been greatly exaggerated. Like-mindedness … contributes little or nothing to national solidarity" (Park, 1914; reproduced in Park and Burgess, 1924: p. 759). Instead, Park and Burgess argued,

> Not by the suppression of old memories, but by their incorporation in his new life is assimilation achieved … Assimilation cannot be promoted directly, but only indirectly, that is, by supplying the conditions that make for participation. There is no process but life itself that can effectually wipe out the immigrant's memory of his past. The inclusion of the immigrant in our common life may perhaps best be reached, therefore, in cooperation that looks not so much to the past as to the future. The second generation of the immigrant may share fully in our memories, but practically all that we can ask of the foreign-born is participation in our ideals, our wishes, and our common enterprises.
>
> 1924: pp. 739–740

Ironically, despite his wide-ranging writings on many subjects, Park may be best known for the formulaic notion that assimilation is the final stage of a natural, progressive, inevitable, and irreversible 'race relations cycle.' But in a prolific career, Park only wrote about a 'race relations cycle' twice: first in a single sentence near the end of a 1926 article, "Our Racial Frontier in the Pacific"; then a decade later in a brief introduction to a book on interracial marriage in Hawaii written by one of his former students. In the first instance, he was arguing against the likelihood that a 'racial barrier' – which the passage of exclusionary laws sought to establish by barring Asian migration to the United States – could be much of a match against global economic, political, and cultural forces that have brought about "an existing interpenetration of peoples … so vast and irresistible that the resulting changes assume the character of a cosmic process" (Park, 1926: pp. 141, 149). And in his 1937 introduction, he explicitly rebutted any notion of a unilinear assimilative outcome to race conflict and change ("what are popularly referred to as race relations"), arguing instead that when stabilization is finally achieved, race relations would assume one of three configurations: "They will take the form of a caste system, as in India; they will terminate in complete assimilation, as in China; or the unassimilated race will constitute a permanent racial minority within the limits of a national state, as in the case of the Jews in Europe … All three types of change are involved … in what we may describe as the 'race relations cycle'" (Park, 1937: xiii).

What has come to be called 'straight-line theory' (see Gans, 1992a,b) has little basis in the theories of Park or Gordon, as is often if mistakenly asserted, but gained traction from W. Lloyd Warner and Leo Srole's *The Social Systems of American Ethnic Groups*, a definitive statement on the subject published in 1945. (The data, collected in the early 1930s, formed the basis of Srole's 1940 doctoral dissertation, "Ethnic Groups and American Society: A Study in the Dynamics of Social Assimilation."). They described the progressive advance of eight European-origin groups in the major status hierarchies of 'Yankee City' (Newburyport, Massachusetts): the Irish, French Canadians, Jews, Italians, Armenians, Greeks, Poles, and Russians. In the immigrant generation, all except the Jews had come from rural backgrounds. From the first chapter ("The Melting Pot," consisting of seven illustrative personal stories) to the last ("The American Ethnic Group"), the book systematically analyzed their spatial distribution, economic life, class system, family, church, language and the school, and associations, and spelled out a set of innovative methods for the study of ethnic groups.

Warner and Srole developed six-point linear indices to measure residential, occupational, and class status; and 'assimilation' and 'subordination' scales based on specific criteria to estimate the time for an entire group to disappear (the final result of assimilation), the proportionate number of people who drop out of a group in each generation, and the amount and kind of participation permitted members of the group by the 'host society.'

They explicitly linked upward social mobility to assimilation, which they saw as determined largely by the degree of ethnocultural (religion and language) and, above all, racial difference from the dominant group. While 'racial groups' were subordinated and excluded through caste restrictions on residential, occupational, associational, and marital choice, the clash of 'ethnic groups' with the dominant institutions of the host society was not much of a contest, particularly among the young. The industrial economy, the polity, the public school, popular culture, and the American family system all undercut and absorbed ethnicity in various ways, so that even when "the ethnic parent tries to orient the child to an ethnic past … the child often insists on being more American than Americans" (1945: p. 284). For the upwardly mobile, with socioeconomic success came intermarriage and the further dilution of ethnicity. They concluded that "it is the degree of racial difference from the white American norms which counts most heavily in the placement of the group and in the determination of its assimilation"; absent such discrimination and structural inequalities, however, "the future of American ethnic groups seems to be limited; it is likely that they will be quickly absorbed" (pp. 294–295).

That general if qualified view of assimilation as linear progress, with sociocultural similarity and socioeconomic success marching in lock step, was reformulated by Milton Gordon in *Assimilation in American Life* (1964), published ironically on the eve of the beginning of the latest era of mass immigration to the United States – and of the denouement of the concept itself in the wake of the 1960s. From the opening sentence of the book, Gordon focused on the relational and contextual character of the process: "This book is concerned, ultimately, *with problems of prejudice and discrimination arising out of differences in race, religion, and national background* among the various groups, which make up the American people" (p. 3; emphasis added).

Although he meticulously reviewed a wide variety of definitions of 'assimilation' in the scholarly literature, he did not explicitly provide his own. Instead, he broke down the assimilation sequence into seven steps, of which 'identificational assimilation' – a self-image as an unhyphenated American – was the end point of a *hypothetical* process that began with cultural assimilation, proceeded through structural assimilation and intermarriage, *and* was accompanied by an absence of prejudice, discrimination, and value conflict in the 'core society.' Once structural assimilation occurred (i.e., extensive primary-level interaction with members of the 'core group'), either in tandem with or subsequent to acculturation, "the remaining types of assimilation have all taken place like a row of tenpins bowled over in rapid succession by a well-placed strike" (1964: p. 81). For the children of white European immigrants, at least, the acculturation process was so 'overwhelmingly triumphant' that the greater risk consisted in alienation from family ties and in role reversals of the generations that could subvert parent–child relationships.

Nonetheless, in reviewing the actual evidence for the assimilation sequence in American life, Gordon reached very different conclusions than those that are habitually ascribed to him. He coined the term 'ethclass' to refer to the stratified segment of social space created by the intersection of ethnicity and social class, which he saw as "fast becoming the essential form of the subsociety in America" (p. 51), and proposed a series of hypotheses about contextual variations in cultural behavior, social participation, and group identity. He found that "The most salient fact … is the maintenance of the structurally separate subsocieties of the three major religions and the racial and quasi-racial groups, and even vestiges of the nationality groupings, along with a massive trend toward acculturation of all groups – particularly their native-born – to American culture patterns." In short, "the sense of ethnic belonging has survived … American society has come to be composed of a number of 'pots' … The entire picture may be called a 'multiple melting pot'" (24–25, 67, 130–131). Anticipating what 'segmented assimilation' would assert in the 1990s, he concluded that "Structural pluralism is the major key to the understanding of the ethnic makeup of American society, while cultural pluralism is the minor one" (p. 159).

Gordon was aware of the ways in which the real and the rhetorical, the ideal and the ideological, get wrapped up in the idea of assimilation. 'Cultural pluralism' as an ideology did not match empirical realities, and the theory of the 'Melting Pot' exhibited "a considerable degree of sociological naiveté" (p. 129). And while 'Anglo-conformity' was the most prevalent ideology of assimilation in American history, he also noted that "Structural assimilation turned out to be the rock on which the ship of Anglo-conformity foundered. And if structural assimilation, to a large degree, did not take place, then in similar measure amalgamation and identificational assimilation could not" (p. 114).

Historians have seen the apogee of the concept of assimilation in the 1950s and early 1960s as reflecting the need generated by World War II for national unity, and the postwar tendency to see American history as a narrative of consensus rather than conflict; and the political and social upheavals of the 1960s (nationally and internationally) as shattering the 'consensus school' and the rationale for studying assimilation, bringing back instead a focus on the ethnic group and ethnic resilience, and more inclusive conceptions of American society. As the notion of an Anglo-American core was delegitimized amid the conflicts and ethnic reassertions of the 1960s, assimilation lost its allure (Kazal, 1995). But by the 1990s, once more well into a new era of mass immigration, a systematic reevaluation of the concept of assimilation emerged, with applications in contemporary scholarship seeking to contrast differences and similarities between the old and the new immigration.

Incorporation Processes: Acculturation, Integration, Identification

Combining the various emphases currently given to the term, 'assimilation' involves a series of interrelated but analytically

distinct cultural (acculturation), structural (integration), and psychological (identification) dimensions. Gordon referred to them as "the three crucial variables of group identity, social participation, and cultural behavior as they pertain to the subsociety of the ethclass" (1964: p. 51). These processes do not unfold in a social vacuum; contextual and group factors shape each of these dimensions either by promoting or precluding assimilative outcomes (Yinger, 1981, 1994; Massey and Sánchez, 2010). In the end, there can be no 'assimilation' without acceptance and inclusion by the dominant society.

Acculturation, which comes closest to the common sense notion of 'melting,' involves complex processes of cultural diffusion and changes producing greater linguistic and cultural similarity between two or more groups. Its homogenizing influences are generally more extensive among members of smaller and weaker groups, and particularly (voluntary) immigrant groups – and more rapidly achieved with respect to what Gordon called 'extrinsic culture traits.' Nonetheless, acculturation is never exclusively one-sided; dominant groups too are culturally influenced by their contacts with other ethnocultural groups in the society (Alba and Nee, 2003). In the American experience, language shifts have been overwhelmingly one-sided, with the switch to monolingual English typically being accomplished by the third generation. Acculturation proceeds more rapidly among children than adults, and linguistic and other acculturative gaps commonly develop in immigrant households between parents and children; Portes and Rumbaut (2001) have identified three such acculturative patterns in parent–child relationships, labeled *dissonant*, *consonant*, and *selective acculturation*.

At the individual level, a key distinction is between *subtractive* (or *substitutive*) *acculturation* and *additive acculturation*. The first is essentially a zero-sum game that involves giving up some elements of a cultural repertoire (such as language and memory itself), while replacing them from another; the second does not involve losing so much as gaining to form and sustain a more complex repertoire (bilingualism and biculturalism). Available research has yet to examine systematically the multiplicity of conditions and contexts yielding subtractive versus additive acculturative outcomes, although in the United States at least it has proved exceedingly difficult to sustain fluent bilingualism beyond the second generation (Portes and Rumbaut, 2014).

The degree of acculturation, as noted earlier, is by itself not a sufficient condition for 'assimilation' (the two terms are not synonymous but are often used equivalently; see Gans, 1997). *Structural integration* was the crux of the matter for Gordon, although what he had in mind was the entrance of the minority group into "the social cliques, clubs, and institutions of the core society at the primary group level" (not 'parity' with the majority group on such indices as income or education, or 'regression to the mean' – notions of standardization implicit in uses of 'assimilation' as an intransitive verb). Given the many different institutions involved – and the fact that integration into the economy, the polity, and the community at the secondary group level is ignored by that formulation – a conceptual distinction can be made between *primary* and *secondary* dimensions. The latter refers to a wide range of integrative processes within secondary groups, including socioeconomic and spatial (residential) integration, and the acquisition of legal citizenship as a full-fledged member of the polity. The former – extensive interaction within personal networks and primary relationships, including intermarriage – is unlikely to take place under conditions of status inequality. While all of these dimensions (acculturation, integration, intermarriage) are interdependent to varying degrees, the linkages between them are historically contingent and will vary depending on a number of factors, notably social class, racial framing, and the context of reception within which different groups are incorporated.

Conventional accounts of shifts in ethnic *identification* among the descendants of European immigrants, conceived as part of a linear assimilative process, have pointed to the 'thinning' of their ethnic self-identities in the United States. For their descendants, at least, one outcome of widespread acculturation, social mobility, and intermarriage with the native population was that identity became an optional form of 'symbolic' ethnicity (Gans, 1979; Alba, 1990; Waters, 1990). As the boundaries of those identities become blurred and less salient, less relevant to everyday social life, the sense of belonging and connection to an ancestral past faded – into what Richard Alba called "the twilight of ethnicity." This mode of ethnic identity formation, however, was not a simple linear function of socioeconomic status and the degree of acculturation – i.e., of linguistic and other cultural similarities with the dominant group – but hinged also on the context of reception and the degree of discrimination and racialization experienced by the subordinate group.

Identity shifts, like acculturative changes, tend to be from lower to higher status groups. But where social mobility is blocked or hindered by prejudice and discrimination, members of lower status groups may react by reaffirming their shared identity. This process of forging a *reactive ethnicity* in the face of perceived threats, persecution, discrimination, and exclusion is not uncommon (Portes and Rumbaut, 2001). On the contrary, it is another mode of ethnic identity formation, accounting for the 'thickening' rather than the dilution of ethnicity. At the extreme, as reflected in the African-American experience, the result can be the sense of 'double consciousness' of which W.E.B. DuBois wrote eloquently.

Compared to language loyalty and language shift, generational shifts in ethnic self-identification are far more conflictual and complex. Paradoxically, despite the rapid acculturation of European immigrants in the United States, as reflected in the abandonment of the parental language and other ethnic patterns of behavior, the second generation remained *more* conscious of their ethnic identity than were their immigrant parents (Nahirny and Fishman, 1965). The parents' ethnic identity was so much taken for granted that they were scarcely explicitly aware of it, but the marginality of their children made them acutely self-conscious and sensitive to their ethnicity, especially when passing through adolescence. Moreover, as parents and children acculturated at different rates, a generational gap grew so that by the time the children reached adolescence 'the immigrant family had become transformed into two linguistic subgroups segregated along generational lines.' Finally, by the third generation 'the grandsons became literally outsiders to their ancestral heritage,' and their ethnic past an object of symbolic curiosity.

Contemporary Realities: Prospects and Paradoxes

By the late-twentieth century, a new era of mass immigration, now overwhelmingly non-European in composition, had again raised familiar questions about the 'assimilability' of the newcomers and their children, and concerns that many of them might become consigned to vast multiethnic formations on the other side of new color lines. Gans (1992a) questioned the American myth of nearly automatic immigrant success and delineated six theoretical 'scenarios' for the incorporation of the new second generation as they were beginning to enter the workforce, hinging on economic and other conditions. Three were positive scenarios, positing upward mobility driven by educational attainment, ethnic succession, or niche improvement. Three posited negative futures, projecting the reverse of the previous three (educational failure, the stalling of ethnic succession in the legal economy, niche shrinkage) – a 'second-generation decline' potentially exacerbated by a combination of economic downturns or nonlabor-intensive economic growth, the second generation's refusal or inability to accept the jobs their parents held, and competition from successive new waves of immigrants. Rather than experiencing upward mobility, the second generation (or segments of it, especially the children of undocumented immigrants) would join the ranks of urban poor.

The new realities also raised questions about the applicability of explanatory models developed in connection with the experience of European ethnics, despite the fact that contemporary immigrants were being incorporated in a post-Civil Rights context – if also officially categorized by new and pervasive pan-ethnic labels – characterized more by ethnic revivals and identity politics than forced Americanization campaigns. While assimilation (as indexed by acculturation, socioeconomic mobility, residential integration, naturalized citizenship) may still represent a 'master trend' for many of today's immigrants, as Alba and Nee (2003) have argued, it is subject to too many contingencies and affected by too many variables to render the notion of a relatively uniform and straightforward path convincing (aside from the swift switch to English among immigrants' children, which cuts across all classes and nationalities).

Instead, as Portes and Zhou (1993) framed it a year after Gans' six scenarios, the present second generation of children of immigrants can be seen as undergoing a process of 'segmented assimilation' where outcomes vary across immigrant minorities, and where rapid integration and acceptance into the American mainstream represent just one possible alternative. Why this is so hinges on a number of factors: internal characteristics, including the immigrants' level of human capital and the structure and cohesiveness of their families, interact in complex but patterned ways with external contexts of reception – government policies and programs, the economy in areas of settlement, employer preferences in local labor markets, the extent of racial discrimination and nativist hostility, the strength of existing ethnic communities – to form the conditions within which immigrants and their children adapt to different sectors of American society.

'Segmented assimilation' processes – i.e., adaptations that take place within varying opportunity structures and are shaped through differential associations, reference groups, experiences, and attachments, especially in primary social relationships stratified by race, religion, region, and class – are not new in the American experience (Rumbaut, 1997). Caste restrictions based on race (extending to all aspects of social life, including citizenship), the 'triple melting pot' of religion-bounded intermarriages, the structural pluralism of 'ethclasses,' the persistence of ethnic groups as political interest groups, are all indicative of such adaptations. Alba and Nee (2003), thinking about the divergent outcomes that will likely obtain in the first decades of the twenty-first century, concede the point and put it well:

> The contemporary immigration scene displays complex, contradictory patterns, from rapid assimilation apparent among some professionals and their children to the new way of sojourning apparent in some transnational circuits, and to the potential among other immigrant groups for incorporation as racialized minorities … Clearly, assimilation will not apply to all immigrant minorities to the same extent … many in the second generation are likely to experience upward mobility into the American socioeconomic mainstream … [others] may experience lateral or, at best, short-distance mobility … Children of low-wage labor migration are likelier to experience downward mobility into the urban minority underclass than children of human capital migration from the same ethnic group … There is no reason to believe that assimilation is inevitable or that it will be the master trend for all these diverse groups (pp. 50, 273–275).

Immigration and American Pluralism

Despite the grand narratives of modernization, which undergird the concept of assimilation, neither race nor religion nor ethnicity has vanished in American life. Protestants (never a homogeneous category, composed of dozens of disparate denominations and of fundamentalist, evangelical, and apostolic varieties) are actually a 'vanishing majority,' having fallen below 50% for the first time in 2005 – a decline that is sharper still among younger people, in more recent years, and among the first and second generations. The U.S. Supreme Court is now made up of six Catholics and three Jews – not a Protestant among them. But religious pluralism remains alive and well. Catholics have remained a fourth of the population for decades now, a secular decline over time having been more than compensated by new influxes of immigrant Catholics from Latin America, the Philippines, and Vietnam. And there has been an increase in non-Christian religions, notably Buddhists, Hindus, and Muslims; aside from the long-present Jewish population, all other non-Christian religions had increased to about 5.5% of the population by 2000. The United States remains today a profoundly religious country – not least because the American state allowed immigrant groups to develop their own social and cultural institutions, including parishes, schools, hospitals, temples, and synagogues – a *laissez faire* stance now ironically attributed to the American ability to 'assimilate' them (Portes and Rumbaut, 2014).

The fate of immigrant languages other than English is another matter: linguistic 'Anglicization' and other forms of acculturation do proceed rapidly, especially among immigrant children and the second generation, and that may be truer now

than ever before, despite the unprecedented diversity of class, culture, and color in the present era of mass immigration. The United States has been aptly described as a 'graveyard' for languages because of its historical ability to extinguish the mother tongues of immigrants within two or three generations (Portes and Rumbaut, 2014). As documented consistently and compellingly by a variety of sources, including census and survey data, not even Spanish appears to challenge this dubious reputation.

But alongside undeniable upward social mobility from the first to the second generation for most groups, especially the children of the poorest and least educated – though the gains appear to peak in the second generation and decline or plateau thereafter (Telles and Ortiz, 2008) – there is compelling evidence of widening 'ethclass' and legal inequalities, of new conflicts and political mobilizations around ethnic and racial issues, and of downward mobility and marginalization for vulnerable segments of these populations. An undocumented status has become a castelike master status blocking access to the opportunity structure and paths to social mobility for millions of immigrants. A fraught concept like 'assimilation,' weighted by the normative baggage of its past and by its insistent if inclusive expectation of progress and homogenized national cohesion, seems ill-suited to grasp these complex dynamics and to focus critical attention on enduring structural inequalities and persistent ethnic and pan-ethnic formations in a 'permanently unfinished' society.

Abstract

In this article, using some of the tools provided by the history and the sociology of science, we assess how scientific societies and scholarly associations emerged and played a role in the development of social and behavioral sciences and in their specialization. They institutionalized in the nineteenth century and became both professionalized and internationalized in the twentieth century. Their number has rapidly grown in most countries. However, even as they multiplied, scientific societies in the social sciences became less important for the scientific enterprise. We analyze this process of internationalization and the role some professional scholarly associations are likely to play in the future as civic actors at national and international levels.

Scholarly associations are one among the various types of social organizations for scientific activity alongside universities, institutes, research laboratories, or learned societies. They are private or government sponsored organizations whose individual or institutional members pursue only one particular or a few related branches of learning. They originally played a key role in the emergence of science and have represented an important factor for the birth and growth of social and behavioral sciences (SBS) since the beginning of the nineteenth century. In particular, scholarly associations have been central to the specialization and discipline wise organization of scientific activities. Yet for more than a century now, they have become more often places of communication and exchanges than sites for producing knowledge. Despite their acknowledged role in the development of the SBS, little research has been done on scholarly associations in the SBS. Studies of science have focused mostly on universities, academies, and learned societies. Scholarly associations have been dealt with sometimes for their role in the history of the natural sciences. Studies dealing with scholarly associations in the SBS are very rare. A majority of the few existing ones focus on their internationalization.

According to the *World Guide to Scientific Associations and Learned Societies* (2006) there are at least 17 500 such associations. Even as this figure includes some research laboratories, it probably underestimates the number of scholarly associations since it depends on self-declarations. In contrast to most professional associations, academies are exclusive organizations, the membership of which is generally restricted to elected fellows. A majority of contemporary scientific associations in any field of science are local, national, and regional and are usually devoted to a specific discipline (Kiger, 1993). There are also a lot of international disparities in the distribution of scholarly associations: the western countries have a lot more of them than countries of the developing world which sometimes have fewer than five science associations (Union of International Associations, (1989), quoted in Crawford, 2003). In the peripheral countries, national scientific infrastructure may be very weak. In that case international scholarly associations are likely to be the main link of scientists to the activities of their field. All the disciplines of the SBS and some of their subdisciplines and cross-disciplines developed their professional associations at both national and international levels.

Early History

While specialized scholarly associations started to develop from the nineteenth century onwards, associations of scholars existed much earlier. One could trace their existence to Confucian China or to Ancient Greece. But this type of intellectual groups started to choose scientific cooperation as a norm much later in history (Zilsel, 2000[1945]). The ideal of cooperation and progress of knowledge through cooperation did not exist in western and nonwestern philosophical traditions before the beginning of the sixteenth century. Conflict was more important than cooperation both in ancient philosophical schools and in medieval universities. According to Edgar Zilsel, "the Middle Ages produced one co-operative scholarly organization. Soon after his accession to the throne in 1252, King Alphonso X of Castile and Leon appointed a commission of Arabic, Jewish and Christian scholars to translate astronomical and astrological works from Arabic to Spanish." They produced the *Libros del Saber* (Zilsel, 2000 [1945]).

In humanist academies, which started to develop in Italy after 1500 (around 700 of them arose in the sixteenth century alone), individualistic ideals were still dominant among members. Moreover, most of these numerous academies were not oriented toward research: they were debating clubs and literary societies for nonscholars, for aristocrats with a high level of education and a variety of interests. Collective work started at least in two places at that period: in the Academia Aldina of Venice founded in 1495 by the printer Aldo Manunzio and in the Academia della Crusca founded in 1582 in Florence. In the former, members were not aristocrats but classical scholars. In the latter, members worked on the first dictionary of Italian language published in 1612, which is thus considered by Zilsel as "the first scientific publication composed by several authors in collaboration … after the astronomical encyclopaedia of the Alphonsine Commission." But the idea of progress through collective cooperation in

research was still absent from this academy. On the other hand, the Accademia del Cimento created by pupils of Galileo in Florence in 1657 was presumably the first association where scientific experimentations were the main goals (Maylender, 1926–1930).

A few years later the Royal Society of London and the Paris Académie des Sciences were created (Ornstein-Bronfenbrenner, 1928). There the Baconian idea of scientific progress was integrated. In London, the small group of original founders expanded to 200 fellows in 1666 to raise more funds. In Paris, the early Academy consisted of two dozens of paid scientists who met privately twice a week. Networks of correspondents sharing the same interests in natural philosophy and science also developed all over Europe in the second half of the seventeenth century. All these new institutions were created outside universities, where in most cases, scholarly activities involved neither any experiments nor any renewal of knowledge: the higher faculties of the medieval and early modern universities only delivered degrees for the liberal professions (theology, law, and medicine). In the case of the Royal Society and the Paris Academy, their relative autonomy toward the patron and monarch was higher than in Renaissance Italian academies. With these associations of aristocrats and scholars, the scientific revolution had its deepest roots in an organizational revolution of intellectual activities. In addition to the Royal Society and the Paris Academy, many other scientific societies were founded in the second half of the seventeenth century, many of which were modeled after one of their two predecessors. In 1669/1670 Leibniz wrote for example a plan for a German Academy that was created in Berlin in 1700. Other academies were later established in Göttingen or in Bavaria.

Modern History

National and local scientific academies spread over Europe as well as in Russia and in the United States during the eighteenth century (McClellan III, 1985). After the French Revolution, the Directoire established in 1795 the Institut National des Sciences et Arts in order to replace the Académie of Sciences. It was divided into three classes of knowledge, one of which would be related today to the SBS and was being called at the time 'Sciences Morales et Politiques.' This class itself was subdivided into six sections: Analysis of Sentiments and Ideas, Ethics, Social Science and Legislation, Political Economy, History, and Geography (Machlup, 1982: p. 92). The French Academy was one of the first scientific institutions where the SBS were recognized as a class of knowledge and where scholars would gather to debate on social scientific topics. A scientific society devoted to anthropology, the *Société des observateurs de l'homme* was also created in Paris a few years later but lasted only for 5 years. In 1803, Napoléon abolished the class for Moral and Political Sciences in the Institute. Almost 30 years later, a national academy again devoted to this class of knowledge was created under the new regime of Louis Philippe of Orléans. It had five sections: Philosophy; Ethics; Legislation, Public Law and Jurisprudence; Economics, Statistics and Finance; and History and Geography (Machlup, 1982: p. 93). There was no comparable move in England until 1902 when the British Academy for the Promotion of Historical, Philosophical and Philological Studies was created because the Royal Society took no interest in the new human and social sciences. In Germany, the scientific academies had devoted some of their sections to philosophy and history since the mid-eighteenth century. In Sweden, the Royal Academy was founded in 1741 and in 1799, one of its 12 classes was devoted to 'economic, statistical, and social sciences.' In most cases, the various disciplines of the SBS except law, history, and geography were fully recognized in public academies at the beginning of the twentieth century, starting with psychology and anthropology.

Scientific societies and scholarly associations outside academies had proliferated in the nineteenth century. Academies remained multidisciplinary and developed in provincial cities. On the contrary, scientific societies became more and more specialized, like the Geological Society of London founded in 1807. They progressively defined norms for realization, presentation, belonging, and qualification among scholars sharing the same interests. Science became, through scholarly associations, a professional activity and a career. The conception of a professionally qualified person replaced the idea that science could only be pursued by a minority with a vocation and money to sustain it. When the British scholar William Whewell coined the word 'scientist' in 1833, he captured the transformation in the definition of the 'man of science' that was taking place at the time. Scientific societies became more elitist both in the physical and in natural sciences and in the SBS. As a result, learned societies, which were more open and public, also developed in the nineteenth century. According to Fox, there were, for example, 665 of them in France in 1886 and a French learned society had a membership of 200 000 on the eve of World War I. Archeology and local history were among the most common interests of these societies (Fox, 1980).

Scientific societies and scholarly associations of the nineteenth century became a central element in the building of a new social organization of higher learning and of science where teaching, research, and the public involvement of scientists were integrated in disciplines. According to Heilbron, "French developments in the natural sciences formed the centre during the first phase of the development of disciplines. If the pioneering role of the French setting is generally overlooked, this is mainly because historical analyses commonly focus on universities while ignoring the role of institutions like academies, learned societies, and professional schools that did not have a university status" (Heilbron, 2004). This was a long-term process, which also involved the founding of chairs in universities, the creation of disciplinary journals, and subsequently creation of autonomous degrees (Daston, 1998; Heilbron, 2004; Kelley, 1997). Nevertheless, from the end of the nineteenth century onwards, scientific societies tended to be less and less implied in learning and research and more in the diffusion of knowledge among scientists and in the public. They were eclipsed by universities and corporate and government laboratories. While scientific societies and academies were devoted to research and universities to teaching and diffusion of science, the roles of these two types of institutions gradually interchanged during the second half of the nineteenth century.

Various interpretations have been made of the emergence of scientific societies and scholarly associations and of their multiplication, specialization, and professionalization. Zilsel has emphasized the technological and social origins of the ideas of cooperation and progress in the first associations of scholars during the sixteenth and seventeenth centuries (Zilsel, 2000 [1945]). He showed that craftsmen on the one hand and cartography, navigation, and applied mathematics on the other hand were decisive for the development of some of the earliest scientific academies and for the invention of the scientific role. The growth in the number of academic societies and in their interest for science has also been related to technology by other scholars (Ornstein-Bronfenbrenner, 1928). Analyzing the data gathered by Maylender on hundreds of European academies created after 1500, Ben David has shown that in the sixteenth and seventeenth centuries the recognition of an autonomous scientific enterprise was more likely in Northern Europe than in Italy (Ben-David, 1971). He thus relates the early developments of scientific societies with Protestantism. Stichweh tried to explain the organization of the modern scientific system and the development of science and scholarly associations in the eighteenth and nineteenth centuries by studying German physical sciences between 1740 and 1890. According to him encyclopedic and humanistic ideals have been replaced by scientific disciplines over this period. The multiplication of professional scientific associations and learned societies in the beginning of the nineteenth century is the first sign of a transformation that can be interpreted as an internal differentiation of knowledge following the social rules of a growing division of labor (Stichweh, 1984). Yet, for other scholars like Heilbron "the world of higher learning already had a fairly differentiated structure well before the second half of the eighteenth century…Science and scholarship in Europe was institutionally more heterogeneous before 1800 than after" (Heilbron, 2004). Even though there is no consensus on the factors that provoked the emergence, the multiplication, and the growing specialization of science associations in the western modern world, most of the scholars agree that they were central in the building of a 'regime of disciplines' both in physical and natural sciences and in SBS (Heilbron et al., 1998).

Internationalization and Current Developments

Development of scholarly associations did not stop at national boundaries. First, trans-boundary science existed before the nation-state: from as early as the late seventeenth century, 'international' forms of scientific gatherings and networks emerged. More modern forms of these gatherings took the shape of a few punctual congresses revolving mostly around the discipline of physics. In the nineteenth century, international congresses developed in the SBS including statistics (1853), prehistory (1866), geography (1871), psychology (1889), and history (1900). Universal exhibitions also played a role in the internationalization of scientific traditions and national associations. After 1850, the number of such congresses started to grow at an exponential pace as these gatherings became more diversified at the disciplinary level, with both natural (e.g., physicists and biologists) and social scientists (e.g., demographers and geographers) organizing such events. Several disciplines, such as statistics, set out to hold congresses on a regular basis, thereby paving the way for the creation of proper international scholarly associations.

Several international scientific organizations were thus created between the mid-nineteenth and the late twentieth century so that, in 1994, 'there were approximately 350 active international science associations' (Schofer, 1999). Two phases may be identified in their development. The late nineteenth century and early twentieth century was a period of slow growth as it saw the creation of only about 30% of these associations. In the second half of the twentieth century, international science associations grew in number at an accelerated pace as over 70% of them were founded during that period (Schofer, 1999). The revival and renewed expansion of international social science associations occurred after the Second World War, when the United Nations Education, Science and Culture Organization (UNESCO) initiated and funded international disciplinary associations: the International Union of Anthropological and Ethnographical Sciences (1948), the International Sociological Association (1949), the International Political Science Association (1949), the International Economic Association (1949), the International Association of Legal Science (1950), and the International Union of Psychological Science (1951). These international associations vary in their geographical scope and purpose. At the geographical level, they may seek to gather scientists from all over the world or from a specific continent or region. In terms of their purpose, they may be either professional organizations (that seek to promote specific professional interests and scientific knowledge) or socially oriented associations (that seek to support science to "address social problems such as economic development, environmental degradation, war, nuclear weapons, ethics, and so on"). Socially oriented organizations were relatively rare before 1945 (Schofer, 1999).

Several explanations have been put forward to explain the exponential rise in the number of international scholarly associations in the twentieth century and particularly after 1945. The first of these is related to academic development. In this perspective, the growth in the number of organizations is seen as a consequence of the rise in the number of scholars that came with the massification of higher education and the creation of new universities. Correlatively, it is also linked to the increasing fragmentation of scientific knowledge and the diversification of disciplines. The creation of specific scholarly associations is thus a step toward the increasing autonomization and institutionalization of sciences (Clark, 1972).

While this is a key explanation, other factors have also been put forward by the literature. Several authors have highlighted the influence of political actors and contexts on the development of scholarly associations. As eighteenth and nineteenth centuries saw the "emergence of the nation as the structuring unit and the principal arena of scientific activity" (Crawford et al., 1993), state building processes were seen as powerful incentives for the national development of sciences. Sciences contributed to creating a shared national culture and assumed a regulatory function by getting involved, for example, in the standardization of weights and measures. The common interests of scholars and governments officials often resulted in the foundation of new scholarly organizations, as in the case of Germany where "in 1887, the joint interests of physicists,

government officials and industrial leaders in precision measurement and technology led to the creation of the Imperial Institute of Physics and Technology" (Crawford, 1992).

Correlatively, the 'institutionalization of the liberal world polity' is identified as a key factor for the rise in the number of international scholarly associations, notably after World War II (Schofer, 1999). Several studies have, for example, documented the role played by UNESCO in the creation and funding of such organizations, particularly in the social sciences (e.g., Platt, 2002). More recently, the European Union also funded the foundation of regional scientific organizations with a view to strengthening the project of European Research Area (ERA). Some nongovernmental organizations also played a key role in sponsoring the creation of scholarly associations. During the interwar years and the Cold War, philanthropic organizations such as the Ford and Rockefeller foundations indeed provided sizable grants for the founding of several scientific endeavors in all kinds of disciplines ranging from molecular biology (Kay, 1993) to public administration.

On the other hand, other political factors may hamper the creation of scholarly associations. Periods of wars and economic depression tend to decrease the founding rate of professional science organizations (Schofer, 1999). The nature of political regimes may also be more, or less favorable to the development of scientific disciplines and the creation of scholarly associations. Authoritarian regimes have thus been shown to deter the foundation of such bodies (e.g., Blum and Mespoulet, 2003), contrary to liberal democracies.

Becoming Civic Actors?

Some scholars relate the growing internationalization of scientific associations with a change in their social role. Crawford writes, "(we are currently living a) major shift from science associations organized as an inward-looking profession to science associations organized around social problems and societal concerns, often sustaining advisory positions (or other authoritative roles) in relation to the United Nations or particular national governments," as in the case of the International Organization for Chemical Sciences in Development or the International Network of Engineers and Scientists for Global Responsibility (Crawford, 2003: pp. 81–82). These socially oriented scholarly associations provide relevant information on scientific activities to both policy makers and public. They promote science or SBS as means to solve some social issues. They also develop appropriate ethical frameworks for the practice and utility of science. According to Crawford, the "rise of professional science INGOs increases the founding rate of socially oriented science INGOs" (Crawford, 2003: p. 92). After a long phase of specialization, of professionalization, and of internationalization of scientific societies and scholarly associations in the natural and social sciences we may now witness a political turn in their role.

Abstract

Associative learning denotes a specific kind of learning process, in which a change in the behavior of an organism results from adaptation to a particular relation between events occurring in an environment. Current insights in the neurobiological mechanisms subserving associative learning are primarily based on experimental and clinical research with the classical (eyeblink) conditioning paradigms. In the mammalian species, including humans, the cerebellum serves as the cardinal neural substrate for different forms of associate learning including motor, emotional, and cognitive associative learning. This article aims to present a concise overview of the critical involvement of the human cerebellum in associative learning processes in the motor, cognitive, and affective domain.

Introduction

During the past decades, the classical tenet, which posits that the cerebellum, 'the little brain,' solely functions as a coordinator of motor skills has been substantially modified. A large number of neuroanatomical, neurophysiological, neuroimaging, and clinical studies in humans and animals have amassed compelling evidence that fundamentally extends the motor role of the cerebellum to the modulation of a variety of cognitive, behavioral, and affective processes (Baillieux et al., 2008). Although from time to time clinical case descriptions and experimental evidence from animal studies dating back to the early part of the nineteenth century already suggested an association between cerebellar pathology and a variety of nonmotor cognitive and affective dysfunctions, a causal relationship remained unexplored and was dismissed for several decades. However, as exemplified by the work of Snider, Dow, Heath, Cooper, and others (see Schmahmann, 2010 for a review), investigators started in the mid-1900s to examine a possible causal link between the cerebellum and cognitive and affective processes. This line of research laid a robust foundation for the rediscovery of the concept by Leiner et al. (e.g., 1986), who hypothesized that more recently evolved parts of the cerebellum contribute to learning, cognition, and language, and by Schmahmann et al. (see Schmahmann, 2010 for a review), who introduced the influential dysmetria of thought hypothesis providing an historical, clinical, neuroanatomical, and theoretical framework within which a cerebellar role in higher cognitive and affective processes could be considered. In this theory, the cerebellum is viewed as a modulator of behavior function, maintaining it around a homeostatic baseline appropriate to the context. In the same way, the cerebellum regulates motor function (rate, force, rhythm, and accuracy of movements), the speed, capacity, consistency, and appropriateness of affective and cognitive processes. Dysmetria of movement, inherently bound to ataxia of movement, is then matched by dysmetria of thought, an unpredictability and illogic to social and societal interaction. In the late 1990s, Schmahmann and Sherman (1998) introduced in a much cited paper the concept of cerebellar cognitive affective syndrome to identify a range of cognitive and affective disturbances in patients with isolated cerebellar lesions. Based upon bedside screening and formal neuropsychological testing, Schmahmann and Sherman (1998) identified a range of cognitive, linguistic, and affective symptoms following focal cerebellar damage. The core features of this syndrome consist of: (1) executive dysfunctions such as disturbances in planning, set-shifting, abstract reasoning, and working memory (WM), (2) visuospatial deficits, such as impaired visuospatial organization and memory, (3) mild language symptoms including agrammatism and anomia, and (4) behavioral-affective disturbances, consisting of blunting of affect or disinhibited and inappropriate behavior.

Associative learning in its different forms is a good example of the conceptual change of thinking about the role of the cerebellum in motor, cognitive, and affective functioning. Associative learning represents a basic type of learning skill, in which a change in the motor, cognitive, or affective behavior of an organism results from adaptation to a particular relation between events occurring in a particular environment. The paradigm with the longest tradition that attracted ample attention of the scientific community in the research on associative learning is the classical conditioning of the eyeblink response. It was first introduced in a prototypical form in humans by Ernest Hilgard in the 1930s and later popularized during the 1960s in animals as the nictitating membrane/eyelid response by Isadore Gormezano. In this Pavlovian, associative motor learning paradigm an aversive, unconditioned stimulus (US) such as a periorbital shock or corneal air puff is given after the presentation of a behaviorally neutral conditioned stimulus (CS) such as a tone or light. At the onset, the US elicits a reflexive, unconditioned vigorous eyeblink response (UR) while the neutral CS results in no overt motor reaction. In association with repeated, paired stimulus presentations (50–100 pairings), a gradual development of a learned, conditioned eyeblink response (CR) to the CS takes

place consisting of a precisely timed closure of the eye before the time the aversive CS is given.

The most extensive body of evidence on classical eyeblink conditioning has been derived from experimental animal studies (rabbits) but it appears from many cerebellar lesion and functional brain imaging studies that all mammals, including humans, learn this motor association task at similar rates by means of a same neural circuitry, in which the cerebellum plays a cardinal role. Many animal studies have been conducted on the basis of a variety of experimental techniques such as electrophysiological recording of single and multiple units, electrolytic and chemically induced lesions, chemical and physical reversible lesions, neural stimulation, genetic mutations, and pharmacological manipulation. Notwithstanding the fact that an extensive number of neural regions are involved in various aspects of eyelid responses, the primary focus of interest of the majority of research studies and reviews on eyeblink conditioning has been directed to the cerebellum as the primary structure of interest in the acquisition and storage of this type of associative learning. Thompson et al. demonstrated in an important series of neurobiological studies that the dorsolateral interpositus nucleus of the cerebellum ipsilateral to the conditioned eye is the cardinal locus in animals for acquisition and retention of newly acquired eyelid responses, while involvement of the cerebellar cortex during normal acquisition does not seem to be essential (for a review see Woodruff-Pak and Steinmetz, 2000; Thompson, 2005; Lindquist et al., 2013). Studies applying more complicated forms of eyeblink conditioning, such as trace conditioning, which makes use of a stimulus-free time interval between the CS and US, show that in addition to the deep nuclei of the cerebellum-conditioned learning recruits involvement of the hippocampal system and the prefrontal lobe (Delgado-Garcia and Gruart, 2006).

Motor Associative Learning

Eyeblink Conditioning in Animals

There exists a wealth of excellent overviews and surveys, to which the reader can be referred, in which the large amount of animal study data relating to eyeblink conditioning is dealt with in much detail (e.g., Thompson, 2005; Thompson and Steinmetz, 2009). In this survey, a summary of some of the main findings is presented.

First evidence for the involvement of the cerebellum in classical eyeblink conditioning was derived from early experimental lesion studies in animals. Studies showed that decorticated and decerebrated animals, which were trained in the delay eyeblink CR (the offset of the CS overlaps with the US, or is immediately followed by US) before incurring the lesion, retain the eyeblink CR as long as the cerebellum is not structurally affected. Richard Thompson et al. in the 1980s showed that permanent disruption of CRs in trained animals results from damage to the interpositus nucleus of the cerebellum. In addition, permanent abolishment of the skill to acquire and retain the eyeblink CR was also found in association with lesions involving the lateral pontine nuclei, the inferior olive, the red nucleus, and the inferior, middle, and superior cerebellar pedunculi. By contrast, experimental animal studies with lesions of the cerebellar cortex did not produce a similar consistent pattern of eyeblink CR impairment. Ablations limited to lobule VI (located directly above the anterior interpositus nucleus) massively impaired but did not abolish the delay eyeblink CR (Figure 1). Extensive lesions of the intermediate and lateral zones of the anterior and posterior lobe of the cerebellum were associated with a permanent loss of the skill to acquire and retain the delay eyeblink CR. These lesion studies indicate that structural integrity of the olivo-cortico-nuclear loop is a prerequisite for normal acquisition of CR and that the cerebellum may be critically involved in neural plasticity subserving classical eyelid conditioning.

In addition to structural lesion studies, reversible inactivation of brain function together with electrophysiological recordings of neural activity have been frequently applied as efficient research methods to localize memory traces in the brain. Reversible inactivation by means of pharmacological agents (e.g., lidocaine, tetrodotoxin) or cooling has often been used to produce temporary lesions to the major structures and pathways considered to constitute the cerebellar-brainstem circuitry implicated in classical conditioning of discrete responses during acquisition and performance of CR. The development and execution of the eyeblink CR have been considered to result from learning-related increases in neuronal responding within the interpositus nucleus. Electrophysiological

Figure 1 Cerebellar areas hypothesized to be involved in emotional, motor, and cognitive associative learning. I–X = cerebellar lobules according to Schmahmann et al. (2000); anterior lobe = lobules I–V, posterior lobe = lobules VI–X; medial, intermediate, lateral = cerebellar sagittal zones.

recordings in the cerebellar regions, which receive converging CS and US input showed that the Purkinje cells, which represent the sole output of the cerebellar cortex, discharge when the stimuli (CS or US) are presented, resulting in the inhibition of neural firing in the interpositus nucleus via GABA release, preventing a motor response (CR). In addition, it was also demonstrated that the discharge rate of Purkinje cells from the cerebellar cortex (firing rate) either decreased or increased according to a pattern that seemed time-locked to the execution of the behavioral CR. As a result, the excitatory/inhibitory firing rate pattern of the Purkinje cells likely results in the modulation of excitability of the cellular activity of the interpositus nucleus neurons and the subsequent formation of the CR.

In an impressive series of experimental studies using a spectrum of various techniques, Thompson et al. further refined and extended the classic theories of the computational neurobiologists Marr (1969) and Albus (1971), which considered the cerebellum as a favored structure for modeling a neuronal learning system because of its unique modular architecture and its huge number of neurons. Marr (1969) hypothesized that the mossy fibers serve as the environmental input while the climbing fibers of the cerebellum serve as the teaching input in the learning system. Thompson et al. further extended the neurobiological basis of the generation and control of classically conditioned eyelid responses and introduced a basic brainstem-cerebellar circuitry model, in which the interpositus nucleus and lobule VI as well as the anterior lobe of the cerebellar cortex are crucial parts (**Figure 2**). According to this model, sensory information from the CS (typically a tone CS) enters the pontine nuclei via the peripheral auditory system while the sensory information relating to the US (typically consisting of an air puff) is projected via the trigeminal nucleus to the dorsal accessory inferior olive. Simultaneously, the input entering the trigeminal nucleus is sent via the reticular formation to the cranial motor nuclei comprising the nucleus complex of the facial nerve, resulting in the production of the reflexive UR. The CS sensory information reaches the Purkinje cells of the cerebellar cortex and the interpositus nucleus via axons, which originate from the pontine nuclei (mossy fibers), while the US sensory information enters the Purkinje cells of the cerebellar cortex and the interpositus nucleus via granule cell axons originating from the inferior olive (climbing fibers). According to this model, development and execution of the eyeblink CR result from learning-related increases in neuronal responding within the interpositus nucleus. Purkinje cell output from the cerebellar cortex inhibits interpositus nucleus unit excitation and as a result CR performance. The CR pathway projects from the interpositus nucleus to the magnocellular red nucleus and cranial premotor and motor nuclei, including facial (VII), and accessory nerve (VI) nuclei.

However, although many experimental studies clearly indicate involvement of the brainstem and cerebellum in classical eyeblink conditioning, no consensus exists regarding the exact putative role of the cerebellum in this basic form of associative learning. There is ongoing discussion and even disagreement regarding the contribution of the cerebellum to associative learning as the functional neuroanatomical substrate where associative learning processes related to conditioned eyelid responses take place (acquisition and storage) or, alternatively

Figure 2 A simplified cerebellar circuit model for classical eyeblink conditioning from Thompson, R.F., Steinmetz, J.E., 2009. The role of the cerebellum in classical conditioning of discrete behavioral responses. Neuroscience 162, 732–755; with permission. The CS (tone) enters the circuit through the pontine nuclei. The US (an air puff or shock) is projected via the trigeminal nucleus to the inferior olive, and at the same time to the facial nucleus, forming a brainstem pathway responsible for production of the UR. Mossy fibers originating from the pontine nuclei carry CS information, while climbing fibers originating from the inferior olive carry US information into the cerebellum. Nucleus interpositus modulates the neuronal discharges of inferior olivary neurons via the nucleo-olivary pathway. Excitability changes occur in cerebellar neurons that receive input from the CS mossy fibers and US climbing fibers both in the cerebellar cortex and nuclei. The net effect of plasticity in these two areas is to increase interpositus nucleus activity, which may be capable of driving activity in brainstem neurons that control eyeblinking. The visual cortex facilitates the eyeblink conditioning and interacts with the prefrontal cortex and the hippocampus.

as a structure essential in the proper performance of eyelid responses independently of their reflex or acquired nature. In line with the performance hypothesis, Delgado-García et al. contested the basic brainstem-cerebellar circuit model on the basis of a number of inconsistencies with anatomical, kinematic, electrophysiological, and pharmacological evidence (Manto et al., 2012). In a number of studies, Delgado-García et al. do not define the role of the cerebellum in classical eyeblink conditioning as the locus of acquisition and storage of the critical memory trace but as a facilitator of the memory processes involved in the generation of CRs (Sánchez-Campusano et al., 2009).

Eyeblink Conditioning in Patients

Following the rapid progress of fundamental insights in the neural mechanisms subserving associative learning in animals during the second half of the twentieth century, human lesion studies involved the patients with structural cerebral damage and cerebellar dysfunction became of increased interest to further elucidate the neural basis of associative learning. The results obtained in a variety of etiologically heterogeneous patient populations are in accordance with the findings from animal studies, indicating that the cerebellum is crucially implicated in the acquisition and timing of the eyeblink CRs (Gerwig et al., 2007).

Weiskrantz and Warrington (1979) and Serdaru and L'Hermitte (1981) were the first authors who used an eyelid CR paradigm in a clinical population of brain-damaged patients. In these patients with medial temporal and diencephalic lesions, study results disclosed that the rate of acquisition of the eyelid CR was not affected. On the basis of these findings, Weiskrantz and Warrington (1979) concluded that the patients who could not recall the conditioning episodes (e.g., the patients with Korsakoff's syndrome) but were unimpaired with regard to the acquisition of the eyelid CR represent examples of long-term retention in amnesia syndromes. Given the emerging role of the cerebellum as the primary site of plasticity for the eyeblink CR, Salomon et al. (1989) for the first time explored the effects of damage to the cerebellum and related structures in humans on acquisition and retention of the CR. They investigated the acquisition of an eyeblink CR in a 54-year-old woman with a vascular lesion in the pontine region that affected the cerebellar afferents. In agreement with the findings obtained in animal studies and in marked contrast to an age-matched control group of five healthy subjects, significant disruption in acquiring an eyeblink CR to a tone CS and an air puff US was found in this patient, indicating that the cerebellum acts as an essential structure of plasticity for classically conditioned somatic responses. From the fact that their patient could not condition but could recall and describe the conditioning episode including the relation between the tone and the air puff, Salomon et al. (1989) concluded that their patient was an example of disrupted procedural memory with preserved declarative memory.

Subsequent group studies of patients with etiologically heterogeneous lesions of the cerebellum confirmed the findings of disrupted eyeblink conditioning reported in the early case reports. Indeed, during the past two decades eyeblink conditioning has been extensively studied across various clinical populations including patients with defined focal vascular damage of the cerebellum due to stroke (Gerwig et al., 2010) or posterior fossa tumors, primary neurodegenerative disorders of the cerebellum (Timmann et al., 2005), neuropsychiatric disorders including Alzheimer's disease (Woodruff-Pak, 2001); Huntington's disease (Woodruff-Pak and Papka, 1996); schizophrenia (Bolbecker et al., 2009a); bipolar disorder (Bolbecker et al., 2009b); abstinent chronic alcoholism and amnestic Korsakoff's syndrome (McGlinchey-Berroth et al., 1995); obsessive–compulsive disorder (Tracy et al., 1999); patients in a vegetative condition or with minimal consciousness (Bekinschtein et al., 2009), or developmental neurocognitive disorders such as attention-deficit and hyperkinetic disorder (Frings et al., 2010), autism (Oristaglio et al., 2013), and dyslexia (Nicolson et al., 2002). In a 1-year follow-up study, Timmann et al. (2005), for instance, examined delay eyeblink conditioning in 24 patients with genetically defined heredoataxias (spinocerebellar ataxia (SCA) type 6, type 3, and Friedreich's ataxia) and 10 healthy age-matched control subjects. Compared to the control group, the group of cerebellar patients was significantly impaired in various aspects of eyeblink conditioning. In contrast to the controls, no indications of retention and learning across the training sessions were found in the cerebellar patient group. In addition, the patient group showed disturbed timing of CRs. In the cerebellar patient group, the onset and peak of the CRs occurred significantly earlier than in the control group. As a result, the study clearly showed that impaired learning of CRs is a stable finding across multiple learning sessions in patients with degenerative disorders that primarily affect the cerebellar cortex. From an anatomoclinical perspective, patients with circumscribed vascular lesions of the cerebellum constitute the preferred study group to localize the conditioning-dependent learning sites within the human cerebellum. However, due to a lack of stroke patients with isolated lesions restricted to the cerebellar nuclei and circumscribed regions of the cerebellar cortex, human lesion studies are more circumspect with regard to the role of the cerebellar cortex and the deep nuclei in eyeblink conditioning. The first group study comprising a larger number of patients with focal cerebellar lesions was conducted by Gerwig et al. in 2003. In order to test the hypothesis that conditioning of the eyeblink response is distorted in patients with lesions involving the superior cerebellar artery – known to supply the deep nuclei, anterior lobe, and lobule VI of the cerebellum – and preserved in patients with lesions involving the posterior inferior cerebellar artery (PICA), Gerwig et al. (2003) compared eyeblink conditioning in 24 cerebellar stroke patients with primarily unilateral lesions (20/24) including the vascular territory of the superior cerebellar artery ($n = 11/24$) and the vascular territory of the PICA ($n = 13/24$). High-resolution three-dimensional magnetic resonance imaging (MRI) was used to identify the extent of the cortical cerebellar damage (i.e., which lobuli were affected) and the possible involvement of the cerebellar nuclei. In the group of cerebellar patients, the ability to acquire classically CRs was significantly reduced. As expected, conditioning deficits were present ipsilaterally in the patients with unilateral cerebellar lesions. Eyeblink conditioning was significantly reduced on the affected side compared with the unaffected side in patients with

superior cerebellar artery lesions including hemisphere lobules VI and Crus I. In patients with lesions restricted to the PICA territory (i.e., Crus II and below), no significant difference between the affected and unaffected sides was present. If PICA lesions extended cranially into Crus I, eyelid conditioning was significantly impaired on the ipsilateral side. Conditioning deficits were neither significantly different in superior cerebellar-artery patients with pure cortical lesions compared with the patients with additional nuclear impairment nor in superior cerebellar artery patients with unilateral lesions compared with the patients with bilateral lesions. In agreement with the findings obtained in animal studies that demonstrated the acquisition of eyeblink conditioning depends on the functional integrity of the cerebellar cortex, Gerwig et al. (2005) showed that lesions of the lobule VI and Crus I of the cerebellar cortex are sufficient to impair eyeblink conditioning in humans. With regard to the relative contribution of the deep nuclei to eyeblink conditioning in humans, no sound conclusions could be made since no lesions were restricted to the deep nuclei. In a subsequent study, Gerwig et al. (2005) investigated timing of CRs in an etiologically heterogeneous study group of 43 patients and 45 age- and sex-matched healthy control subjects. The study group consisted of 16 patients with pure cortical cerebellar degeneration (SCA type 6 and idiopathic cerebellar ataxia), 14 patients with vascular lesions located within the territory of the superior cerebellar artery, and 13 patients with infarctions within the territory of the PICA. In comparison with the control subjects, CR acquisition rate was significantly reduced and CRs occurred significantly earlier in patients with cortical cerebellar degeneration and lesions of the superior cerebellum. Incidence and timing of CRs was not impaired in patients with lesions confined to the posterior and inferior cerebellum. Voxel-based lesion-symptom analysis disclosed that cortical areas within the anterior lobe (lobule V) were most significantly related to timing deficits, whereas reduced CR incidences were related to more caudal parts (lobule VI) of the superior cerebellar cortex. The study data reveal that different cortical parts of the anterior cerebellar lobe may be implicated in the formation of the stimulus association and appropriate timing of CRs in humans. Several authors suggested that the disrupted process of eyeblink conditioning in etiologically heterogeneous cohorts of patients favors a role for the cerebellum in the pathogenesis of a variety of neuropsychiatric disorders.

Involvement of the cerebellum in eyeblink conditioning is also supported by a number of neuroimaging studies using functional MRI (fMRI) and positron emission tomography (PET) in healthy subjects. An event-related fMRI study conducted by Ramnani et al. (2000) in five healthy subjects provides clear evidence regarding the lateralization and localization of eyeblink conditioning related areas in the cerebellum. Differential delay conditioning was investigated with pseudorandomly presented trials containing auditory CS+ with a corneal air puff US (paired), or without an US (unpaired). In agreement with the findings in animal and human lesion studies, hemodynamic learning-related changes were found in the ipsilateral cerebellar cortex overlapping the medial portion of cerebellar lobule VI and the adjacent area of Crus I.

Summing up, integrity of the cerebellar circuitry seems to be a prerequisite in different forms of eyeblink conditioning in animals and humans. Since defective CR timing and UR amplitude changes cannot account for the acquisition impairments of patients with cerebellar damage, the cerebellum may be considered to be intrinsically involved in associative learning mechanisms.

Nonconditioned Learning and the Cerebellum

The role of the animal and human cerebellum in motor learning and automatization of motor sequences has attracted much attention. Animal studies in the 1970s based on cerebellar ablation, for instance, demonstrated impaired learning of motor sequences (e.g., Bleek and Peters, 1974). In addition, studies of patients with cerebellar lesions focusing on vestibulo-ocular reflex adaptation (Yagi et al., 1981) and learning of hand/arm movements (e.g., Ito, 1986) also consistently revealed cerebellar involvement in motor learning. Subsequent research disclosed that the cerebellum in addition to its role in motor learning is also crucially implicated in various forms of nonmotor learning as well. Fiez et al. (1992) described a patient who had impaired learning in implicit nonmotor learning tasks, consisting of practice-related learning tasks. Molinari et al. (1997) demonstrated that patients with cerebellar lesions also consistently failed to accomplish learning on serial reaction time tasks, in which the participants' responses are based on the spatial position of series of stimuli that either follow a sequence or occur randomly. Quintero-Gallego et al. (2006) studied the performance of children and adolescents with posterior fossa tumor resections on declarative and procedural learning tasks and showed significantly impaired procedural learning, while declarative learning was preserved. Neau et al. (2000) identified impairment in the learning condition of Rey's word list in five patients with isolated cerebellar infarcts in the PICA territory. Gottwald et al. (2004) investigated memory functions in a group of 21 patients with acquired cerebellar lesions by means of the Wechsler Memory Scale-Revised (WMS-R) and found difficulties in 'free-recall' memory subtests ('logical memory' and 'visual reproduction' subtests of the WMS-R).

A number of neuroimaging studies in the early 1990s explored the neuronal substrate of WM. Paulesu et al. (1993) reported bilateral cerebellar activation and simultaneous activation in associative and sensorimotor cortical regions in healthy volunteers during verbal WM tasks. To date, several neuroimaging studies have confirmed cerebellar involvement in verbal WM tasks, which is in accordance with clinical findings. Ravizza et al. (2006), for instance, investigated the role of the cerebellum in both visual and verbal WM tasks in 15 patients with isolated cerebellar lesions of vascular or neoplastic origin and showed that in comparison to the control subjects performance on forward and backward verbal spans was significantly depressed in cerebellar patients. In addition, the cerebellar patients tended to be more impaired on the verbal than on the spatial span tasks, which implies a cerebellar contribution to the phonological loop. Results regarding cerebellar involvement in visuospatial WM tasks are less consistent. Gottwald et al. (2004) found normal results on forward and backward visual memory spans in patients with isolated cerebellar lesions. In addition,

a meta-analysis on functional neuroimaging studies on WM (Wager and Smith, 2003) disclosed that cerebellar activity during spatial WM tasks is very rare, while consistent cerebellar activations are found during verbal WM tasks.

Cognitive Associative Learning

Although there is general agreement about involvement of the cerebellum in motor (associative) learning, the available evidence for a role of the cerebellum in cognitive associative learning is less strong. In one of the pioneer studies that reported cognitive associative learning deficits in cerebellar disorders, six patients with etiologically heterogeneous cerebellar disorders performed a reaction time paradigm, in which they had to learn the predictive value of an original neutral visual stimulus indicating a particular movement to be performed (Canavan et al., 1994). By contrast, Tucker et al. (1996) did not observe impaired visuomotor associative learning in all of the seven patients with cerebellar ataxia. However, various criticisms on methodological issues were raised against the early findings indicating impaired cognitive associative learning in patients with cerebellar lesions. Drepper et al. (1999), for instance, studied the performance on a cognitive visuomotor associative learning task of nine patients with idiopathic cerebellar ataxia in comparison to a matched control group. Subjects were asked to learn an association between pairs of colors and numerals by trial and error. Regardless of the degree of motor deficits, results clearly indicated that, in comparison to the control subjects, the ability to learn the correct cognitive associations was significantly depressed in the patient group, suggesting a contribution of the cerebellum to cognitive associative learning. Although possible confounding factors such as age, education, IQ, and visual memory had been carefully controlled for, the authors argued that the motor execution component of the task (pressing a button) might as well have captured increased attentional resources in the patient group than in the controls. In a follow-up study of nine patients with degenerative cerebellar ataxia and nine healthy controls (Timmann et al., 2010), the authors investigated by means of systematically varying the motor and cognitive load of the learning task whether the deficits in cognitive associative learning were due to increased attentional demands. Since associative learning proved to be unrelated to the motor demands of the task, the authors concluded that the cerebellum contributes to motor-independent processes involved in associative learning. In addition, a few studies (Richter et al., 2004; Thoma et al., 2008) have indicated that cerebellar dysfunction mainly affects more complex types of associative learning. Thoma et al. (2008), for instance, showed in a study with reward-based associative learning tasks with 8 cerebellar stroke patients (6 unilateral lesions = 3 right, 3 left hemisphere, 2 bilateral hemisphere lesions, 2 with deep nuclei lesions) and 24 carefully matched control subjects that impaired verbal paired associative learning was not affected in the patient group at the level of the easy items (semantically related words) and only distorted with regard to the hard items (semantically unrelated items). In a visual reward-based association learning task, in which new associations between abstract symbols and colors had to be formed on the basis of monetary feedback, the learning rates of the patients were similar to those of the control subjects in the (easy) acquisition phase of task but significantly impaired when task complexity increased (reward-based reversal learning). Since the role of the cerebellum in nonmotor associative learning has not been systematically addressed in functional neuroimaging studies or anatomoclinical research based on focal cerebellar lesions, there is currently no convergent evidence in favor of a critical location in the cerebellum that subserves nonmotor associative learning (Bellebaum and Daum, 2011).

Emotional Associative Learning

Because of its widespread reciprocal connections with distant parts of the central nervous system that regulate autonomic, emotional, and affective function, it has long been suggested that the cerebellum forms an intrinsic part of the distributed neural network subserving autonomic, emotional, and affective processing. Fear conditioning, commonly assessed by changes in autonomic and behavioral responses, represents a form of emotional associative learning, in which the vermis and fastigial nucleus of the cerebellum (limbic cerebellum) are considered to play a cardinal role as a part of an integrated network comprising the limbic system (including the amygdala and hippocampus) and the prefrontal cortex. Early electrophysiological recordings in animals and humans revealed that fastigial nucleus and vermal stimulation induce anger and fear-related responses including autonomic (blood pressure, heart rate, and gastric motility), endocrine (pituitary adrenal hormone), and behavioral changes (immobility, freezing, gnawing, and grooming) while vermal lesions decrease these responses (Heath et al., 1974).

Only a scarce number of *in vivo* studies have addressed the role of the cerebellum in emotional associative learning in humans. In these studies, the focus of interest was directed to fear conditioning. Maschke et al. (2002), for instance, studied via a classical conditioning paradigm (with a tone as the CS and an electrical shock to the right index finger as the US) fear-conditioned heart rate and skin conductance responses as measures for autonomic fear responses in five patients with medial cerebellar lesions due to posterior fossa tumor surgery. Consistent with the findings of the lesion studies in animals, the cerebellar patients, in contrast to the five nonlesioned control subjects, did not show a significant decrease of heart rate during fear conditioning. The findings obtained in the few patient studies are supported by a number of functional brain imaging studies in healthy subjects. By means of an fMRI thermal stimulus paradigm, in which subjects learned during the imaging session which of the presented color signaled pain and which signaled warmth, Ploghaus et al. (1999) investigated in 12 healthy subjects the neural activation patterns associated with acute pain stimuli and its anticipation. Pain experience activated the caudal anterior cingulate cortex, the mid-insula, and the anterior cerebellum around the vermis ('pain regions'), whereas learned anticipation to pain activated the anterior medial frontal cortex, the anterior insula, and the posterior cerebellar vermis ('anticipation

regions'). These findings indicate that nearby but albeit distinct cerebellar areas are engaged during fear experience and associative learning. However, recent functional neuroimaging studies have shown that cerebellar involvement in fear-conditioned learning is not restricted to the vermis per se but may also comprise the posterolateral cerebellar hemisphere suggesting that the vermis relates to the autonomic and somatic aspects of fear and the posterolateral region of the cerebellum to the emotional content.

Conclusion

Classical conditioning in animals and humans has undoubtedly contributed to a substantial increase of insights in the neural network subserving various forms of associative learning in the motor, cognitive, and emotional domain. Although the exact neurobiological mechanisms of cerebellar involvement in motor, cognitive, and emotional associative learning remain to be elucidated, enormous progress has been achieved in delineating the neural circuitry involved in eyeblink conditioning as the prototype of motor associative learning. In addition, a variety of experimental, clinical, and neuroimaging studies based on paradigms that closely relate to classical conditioning revealed that cerebellar disorders have a detrimental effect on cognitive and emotional associative learning as well. The contribution of the cerebellum to motor, cognitive, and emotional associative learning may relate to the role of the cerebellum in motor control processing, i.e., correct prediction of upcoming events associated with particular stimuli and/or actions. Overall, cerebellar circuits are growingly recognized as critical associative centers for sensory information seen in a broad sense. Associative learning is another example on the historical progression from a pure motor point of view to a more global sensorimotor contribution for cerebellar modules. Further investigations are still needed in larger groups of patients with circumscribed lesions to identify which parts of the cerebellum are crucially implicated in the various forms of associative learning.

Assortative Mating in the Marriage Market

Aloysius Siow, University of Toronto, Toronto, ON, Canada

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Using data from the 2000 U.S. census, the first part of this article shows how local log odds are used to measure three forms of marriage matching patterns: ethnic endogamy, positive assortative matching by educational attainment, and social exchange between educational attainment and ethnicity. Using the Choo–Siow marriage matching model, the second part of the article provides a behavioral interpretation of using local log odds to measure marriage matching patterns.

In most marriage markets, there are different types of participants. They differ by age, ethnicity, educational attainment, religion, citizen status, and so on. In spite of this large diversity of participants, individuals tend to marry (match with) spouses who have similar characteristics to their own. This commonly observed tendency to marry someone like themselves is known as positive assortative matching (PAM) in marriage.

The first part of this article is to present a simple way to quantify different forms of PAM. The most common way to quantify PAM on one ordered characteristic, such as years of education, is to compute the correlation in the characteristics between husbands and wives (e.g., Fernandez et al., 2005). While useful, such a correlation cannot be used to quantify matching when characteristics are unordered such as ethnicity or religion. It is also less useful when there are multiple characteristics and we want to consider trade-offs between different characteristics.

Sociologists and demographers also commonly use log-linear models (which is a parametrization of contingency tables) to quantify PAM (e.g., Goodman, 1972; Kalmijn, 1991; Mare and Schwartz, 2005 for U.S. data; Blossfeld, 2009; Smits and Park, 2009 have international comparisons). There is confusion about how to define PAM using log-linear models and how to use them to quantify trade-offs between multidimensional characteristics (Gullickson and Fu, 2010). Log-linear models is a parametric class of local log odds models. Instead of using log-linear models, it will be more transparent to work with local log odds models directly (e.g., Gullickson and Fu, 2010; Siow, in press).

We will use local odds models first to quantify endogamy (propensity to marry someone with the same characteristic) for an unordered characteristic. Then we will quantify them to PAM for one ordered characteristic. Finally, we will use them to study trade-offs between two characteristics when individuals are characterized by more than one characteristic. For illustration, we will estimate the various local log odds using marriage matching data from the U.S. 2000 census.

Recently, researchers have investigated whether the degree of PAM by spousal educational attainment in the US has increased in the last 30–40 years (e.g., Mare and Schwartz, 2005; Siow, in press). Within that time period, women have caught up and passed men in average college attainment. Also marriage rates have fallen. These researchers ignore the issue of changes in population supplies and marriage rates when they study changes in PAM over time. They also often study the evolution of educational PAM holding other characteristics of the spouses, such as age and ethnicity, constant. While empirically convenient, is there a behavioral justification for these two empirical shortcuts?

The second part of this article applies Siow which uses the Choo and Siow (2006; hereafter CS) marriage matching model to provide a unified behavioral interpretation of the matching behavior characterized by these local log odds. Conveniently, the CS model shows that one can study marriage matching (1) independent of variation in population supplies and (2) holding other characteristics of spouses constant.

Measuring Endogamy

Individuals differ along different characteristics. Some of these characteristics are ordered. One can have more or less of an ordered characteristic such as age, income, and years of education. Some characteristics cannot be ordered such as ethnicity and religion. It will be convenient first to discuss matching by unordered characteristics.

When a characteristic is unordered, all participants may not rank the desirability of different potential spouses along those characteristics in the same way. Consider the case of matching by religion. An atheist may regard a potential Jewish spouse as similar to a potential Buddhist spouse. On the other hand, a Muslim may rank a potential Jewish spouse differently from a potential Buddhist spouse. With unordered characteristics, we can distinguish between a tendency of each type of spouse to marry their own type (endogamy) versus intermarrying.

Consider the number of spousal matches by ethnicity: White (W), Black (B), and Hispanic (H), in the U.S. 2000 5% census between 31 and 35 years old females and 32–36 years old males in **Table 1**. (For this article, an individual is Hispanic if the person is of Hispanic origin independent of any other racial designation.)

Table 1 Ethnic marital matching in the U.S. 2000 census

		Female		
		White	*Hispanic*	*Black*
Male	White	112 732	3054	315
	Hispanic	2482	15 646	111
	Black	791	265	9608

 http://dx.doi.org/10.1016/B978-0-08-097086-8.31100-X

A striking feature of the table is that preponderance of marriages along the main diagonal of the table which are marriages where both spouses have the same ethnicity (ethnic endogamy or homogamy). One way to quantify endogamy is to measure the number of marriages where both spouses have the same ethnicity relative to ones where one spouse is another ethnicity. The problem with this measure is that although all Blacks in the above table can potentially marry White spouses, not all White spouses can potentially marry Black or Hispanic spouses. Thus, one has to take into account availability of potential spouses in quantifying endogamy or PAM.

Let T the number of different types individuals of each gender in the marriage market. In Table 1, $T = 3$. Let i (j) be the different types of husbands (wives) by ethnicity where i (j) = W, B, H. Let μ_{ij}, the value of the (i, j) cell of Table 1, be the number of type i husbands married to type j wives.

In this article, we will use local log odds ratio to measure local endogamy or PAM. Consider W husbands and wives who are either married to each other or intermarry B spouses. There are $m_{W(W,B)} = \mu_{WW} + \mu_{WB}$ and $f_{(W,B)W} = \mu_{WW} + \mu_{BW}$ of these husbands and wives, respectively. Also consider B husbands and wives who are either married to each other or intermarry W spouses. There are $m_{B(W,B)} = \mu_{BW} + \mu_{BB}$ and $f_{(W,B)B} = \mu_{WB} + \mu_{BB}$ of these husbands and wives, respectively. The sum of the number of husbands and wives must be equal to each other, $m_{W(W,B)} + m_{B(W,B)} = f_{(W,B)W} + f_{(W,B)B}$.

The marriage pattern between Blacks and Whites is described by the local log odds ratio for these marriages, l (W, B), as

$$l(W,B) = \ln\left[\frac{\mu_{WW}\mu_{BB}}{\mu_{WB}\mu_{BW}}\right] \qquad [1]$$

The numerator consists of the product of the numbers of endogamous marriages. The denominator consists of the product of the numbers of intermarriages. Given the number of marriages of one type, and the numbers of husbands and wives of each type, $m_{W(W,B)}$, $m_{B(W,B)}$, $f_{(W,B)W}$, and $f_{(W,B)B}$, the numbers of the other three types of marriages are determined. The local log odds is also determined. Put another way, given the local log odds and the numbers of husbands and wives of each type, the numbers of marriages of each type is determined. Thus the local log odds summarizes all marriage matching patterns which are feasible given the numbers of husbands and wives of each type.

Considering these four types of marriages, random matching of spouses or independence in marriage matching for males of type t and females of type t' implies

$$\mu_{tt'} = m_{t(t,t')}\left(\frac{f_{(t,t')t'}}{f_{(t,t')t} + f_{(t,t')t'}}\right) \qquad [2]$$

Using the above formula for the different types of marriages in eqn [1], the local log odds for random matching of spouses of two different ethnicities, t and t', is

$$l(t,t') = 0 \qquad [3]$$

That random matching implies $l(t, t') = 0$ is important because it says that the distributions of husbands and wives do not constrain the local log odds in a particular way.

Type W and B individuals practice local endogamy if $l(W, B) > 0$ and local exogamy $l(W, B) < 0$. The degree of local endogamy is the value of $l(W, B)$. From Table 1, $l(W, B) = 8.37$ which is far from zero, the criteria for random matching by race.

The value of $l(W, B)$ is independent of the values of $l(W, H) = 5.45$ or $l(B, H) = 8.54$, i.e., any other degrees of local endogamy. Thus for each racial pair, they all practice endogamy.

The total number of local log odds, or local endogamy measures, is $T(T-1)/2$. Since the number of local endogamy measures depends on T, it may be difficult to compare the degree of endogamy across societies or even in one marriage market across time.

Let $\Phi(x)$ be an indicator function such that

$$\Phi(x) = \begin{cases} 1 & \text{if } x > 0 \\ 0 & \text{if } x \le 0 \end{cases}$$

In order to compute an overall measure of endogamy for a marriage market with T types of an unordered characteristic, consider two overall indexes of endogamy:

$$E_T = \sum_{t=1}^{T}\sum_{k<t}\frac{\Phi(l(t,k))}{T(T-1)/2} \qquad [4]$$

$$E_T^W = \sum_{t=1}^{T}\sum_{k<t}\left[\frac{\ln\left(f_{(t,k)t} + f_{(t,k)k}\right)}{\sum_{h=1}^{T}\sum_{g<h}\ln f_{(h,g)h} + f_{(h,g)g}}\right]\Phi(l(t,k)) \qquad [5]$$

E_t is the fraction of local log odds which are strictly positive. E_T^W is a weighted average of the fraction of local log odds which are strictly positive. The log population weighting scheme gives more weight, at a diminishing rate, to types with larger population shares. If we use simple population shares for the weights, E_T^W will be dominated by the local log odds involving Whites. Under random matching, $E_T^F = E_T^{WF} = 0$. When the values of the indexes are larger than zero, we say the society is endogamous.

Let x^y the value of x in year y. In Table 1 with the 2000 census, $E_3^{F2000} = E_3^{WF2000} = 1$. For comparison, in 1980, $E_3^{F1980} = E_3^{WF1980} = 1$. To compute indices which capture whether endogamy has increased, consider

$$\Delta E_T = \sum_{t=1}^{T}\sum_{k<t}\frac{\Phi\left(l(t,k)^{2000} - l(t,k)^{1980}\right)}{T(T-1)/2}$$

$$\Delta E_T^W = \sum_{t=1}^{T}\sum_{k<t}\frac{\sqrt{\omega^{2000}(t,k)\omega^{1980}(t,k)}}{\sum_{h=1}^{T}\sum_{g<t}\sqrt{\omega^{2000}(h,g)\omega^{1980}(h,g)}}\Phi\left[l(t,k)^{2000} - l(t,k)^{1980}\right]$$

$$\text{where } \omega^y(t,k) = \frac{\ln\left(f^y_{(t,k)t} + f^y_{(t,k)k}\right)}{\sum_{h=1}^{T}\sum_{g<h}\ln\left(f^y_{(h,g)h} + f^y_{(h,g)g}\right)}$$

$\Phi(l(t,k)^{2000} - l(t,k)^{1980}) = 1$ when $l(t,k)^{2000} > l(t,k)^{1980}$ and there was an increase in endogamy in the racial pair (t, k) between 1980 and 2000. It is zero otherwise. So the index, ΔE_T, is the fraction of racial pairs where there were increases in endogamy between the two time periods. If endogamy

increased for all racial pairs, $\Delta E_T = 1$. Conversely, if endogamy decreased for all racial pairs, $\Delta E_T = 0$. ΔE_T^W is a weighted fraction of racial pairs where there were increases in endogamy between the two time periods. The weighting scheme gives more weight, at a diminishing rate, to racial pairs with larger population shares.

With the 2000 and 1980 data, $\Delta E_3^F = 0.0$ and $\Delta E_3^W = 0.0$. For all three racial pairs, endogamy decreased between 1980 and 2000. There is no difference between the unweighted and weighted indices. So racial endogamy unambiguously declined in the United States between 1980 and 2000.

Measuring PAM

When a characteristic is ordered such as the age or schooling attainment of an individual, we can measure more than just whether spouses practice endogamy or not. We will consider a more general notion of spousal matching, PAM.

Let each male in the marriage market be characterized by an ordered characteristic i, $i = 1, \ldots, I$, where $i + 1 > i$. Let each female in the marriage market be characterized by an ordered characteristic j, $j = 1, \ldots, J$, where $j + 1 > j$. Let μ_{ij} be the number of type i males married to type j females.

Table 2 shows the number of spousal matches by four categories of schooling attainment, less than high school (*LHS*), high school graduate (*HS*), some college, BA or more (*BA*), in the U.S. 2000 5% census between 31 and 35 years old females and 32–36 less than high school years old males. This is the same population as in Table 1. The value in cell (i, j), μ_{ij}, is the number of type i males married to type j females.

Table 2 shows there is also endogamy by schooling attainment. Individuals are more likely to marry spouses with the same level of education. But Table 2 also shows that individuals are more likely to marry someone closer to themselves in education than further away. So *LHS* individuals are more likely to have *HS* spouses than *LBA* spouses and even less likely to have *BA* spouses. Again we have to worry about feasibility. For example, not every *HS* male can marry an *LHS* female even if he wanted to.

Here, we extend the local log odds concept above to measure PAM. Consider types i and $i+1$ husbands who are married to types j and $j+1$ wives. There are $m_{i(j,j+1)} = \mu_{ij} + \mu_{i,j+1}$ and $f_{(i,i+1)j} = \mu_{ij} + \mu_{i+1,j}$ of type i husbands and type j wives, respectively. There are also $m_{i+1,(j,j+1)} = \mu_{i+1,j} + \mu_{i+1,j+1}$ and $f_{(i,i+1),j+1} = \mu_{i,j+1} + \mu_{i+1,j+1}$ of type $i+1$ husbands and type $j+1$ wives, respectively. The sum of the number of husbands and wives must be equal to each other, $m_{i(j,j+1)} + m_{i+1,(j,j+1)} = f_{(i,i+1)j} + f_{(i,Wi+1),j+1}$.

Table 2 Educational marital matching in the U.S. 2000 census

		Female			
		LHS	*HS*	*LBA*	*BAM*
Male	LHS	7905	5171	3209	713
	HS	3704	19 920	13 070	4249
	LBA	1850	9183	21 945	10 359
	BAM	430	2864	9830	31 133

LHS, less than high school; HS, high school graduate; LBA, some college.

To characterize the marriage matching patterns among these adjacent types, the local log odds ratio for these marriages, $l(i, j)$, is defined as

$$l(i,j) = \ln\left[\frac{\mu_{ij}\mu_{i+1,j+1}}{\mu_{i+1,j}\mu_{i,j+1}}\right] \qquad [6]$$

The local log odds is defined for any (i, j) pair as long as $i < I$ and $j < J$. There are $(I-1) \times (J-1)$ local log odds in total. Note also that I need not equal J. Table 3 shows the all the local log odds computed from Table 2.

As earlier, given the numbers of husbands and wives of each type, $m_{i,(j,j+1)}$, $m_{i+1,(j,j+1)}$, $f_{(i,i+1)j}$, and $f_{(i,Wi+1),j+1}$, and the local log odds ratio, $l(i, j)$, the numbers of marriages of each type is determined. The local log odds summarizes all marriage matching patterns which are feasible given the numbers of husbands and wives of each type. Each local log odds is independent of the values of the other local log odds. Put another way, the marriage matching distribution $\mu_{ij} > 0$, for all i and j, is completely summarized by the $(I-1) \times (J-1)$ local log odds and the numbers of married individuals of each type.

As earlier, when there is random matching between types i and $i+1$ husbands with types j and $j+1$ wives, $l(i, j)$ will be equal to zero. Again, that random matching implies $l\ (i, j) = 0$ is important because it says that the distributions of husbands and wives do not constrain the local log odds in a particular way. If $l(i, j)$ is positive, there is PAM between these adjacent types which says that individuals prefer to marry spouses who are closer to them in characteristic than further away. If $l(i, j)$ is negative, there is negative assortative matching between these adjacent types which says that individuals prefer to marry spouses who are further away from them in characteristic than closer by.

Statisticians say that spouses in a marriage market practice PAM if all $(I-1) \times (J-1)$ local log odds are larger than zero or are totally positive of order 2 (TP2). This is a strong requirement. Following the statistics literature, Siow provides an estimator for all the local log odds which imposes TP2.

Consider the following two overall indexes of PAM for a society.

$$P_{IJ} = \sum_{i=1}^{I-1}\sum_{j=1}^{J-1}\frac{\Phi(l(i,j))}{(I-1)\times(J-1)} \qquad [7]$$

$$P_{IJ}^W = \sum_{i=1}^{I-1}\sum_{j=1}^{J-1}\left[\frac{\ln\left(m_{i(j,j+1)} + m_{i+1,(j,j+1)}\right)}{\sum_{h=1}^{I-1}\sum_{g=1}^{J-1}\ln\left(m_{h(g,g+1)} + m_{h+1,(g,g+1)}\right)}\right]\Phi(l(i,j))$$

Table 3 Local log odds in education matching in the U.S. 2000 census

		Female		
		LHS/HS	*HS/LBA*	*LBA/BA*
Male	LHS/HS	2.11	0.06	0.38
	HS/LBA	−0.08	1.29	0.37
	LBA/BA	0.29	0.36	1.9

LHS, less than high school; HS, high school graduate; LBA, some college; BA, BA or more.

P_{IJ} is the fraction of local log odds which are positive. P_{IJ}^{W} is the weighted average of the fraction of local log odds which are positive. Again we use log population weights to give more weight, at a diminishing rate, to types with larger population shares. When there is random matching in marriage by all individuals, $P_{IJ} = P_{IJ}^{W} = 0$. Using Table 3, $P_{44}^{2000} = 0.89$, $P_{44}^{W2000} = 0.89$. As a point of comparison, $P_{44}^{1980} = 1$ and $P_{44}^{W1980} = 1$. The equivalent indexes for increases in PAM are $\Delta P_{44} = 0.44$, $\Delta P_{44}^{W} = 0.44$. In other words, slightly more than half of the local log odds fell between 1980 and 2000. Thus there is little evidence in favor of an increase in PAM by educational attainment between 1980 and 2000.

Considering changes in educational endogamy, $\Delta E_4 = 0.33$ and $\Delta E_4^{W} = 0.33$. Again here, slightly more than half of the local log odds for educational endogamy fell between 1980 and 2000. Thus there is also little evidence in favor of an increase in endogamy by educational attainment between 1980 and 2000.

Summarizing the empirical evidence, there is evidence in favor of increases in educational PAM and endogamy between the two periods. The weighted indexes do not give quantitatively different results than the unweighted indexes.

Trade-Offs in Multidimensional Matching

There is no standard definition of PAM when individuals are characterized by multidimensional attributes (See Dupuy and Galichon, 2012 for an overall approach). Our goal here is modest and application based. We follow Gullickson and Fu to use local log odds to study status exchange in marriage between Black and Whites (Merton, 1941; Davis, 1941), an important application of multidimensional PAM.

When individuals are characterized by multidimensional attributes, a husband may have a higher value of an attribute X than his wife and a lower value of another attribute Y than her. Sociologists argue that the husband and wife are engaging in social exchange in marriage. Applications of this theory include: A Black husband with a White wife who has lower educational attainment than him. Indian women may offer larger dowries to their husbands who are from a higher caste. A wealthy man may marry a younger beautiful but less wealthy or educated woman as a trophy wife.

Following Gullickson and Fu, consider the case where individuals are characterized by their race ($r = W, B$) and $E_m = E_f = 4$ levels of educational attainment ($e = LHS, HS, LBA, BA$). For notational convenience, let $e + 1$ denote the educational level immediately higher than e. Table 4 shows the numbers of marriages of each match type for the 2000 U.S. census data. An entry in Table 4, μ_{r_m,e_m,r_f,e_f}, is the number of marriages between husbands of race r_m and schooling e_m, and wives of race r_f and schooling e_f.

A striking feature of the data is that significantly more Black men have White wives than Black women have White husbands. Under the social exchange hypothesis, demographers and sociologists hypothesize that some White women intermarry racially for a more educated husband. Equivalently, some educated Black males are willing to marry a less-educated White woman to intermarry White females.

To quantify the above intermarriage phenomena, consider marriages between Black men with education e_m or $e_m + 1$ and White and Black women with education e_f. Both Black and White women have the same level of education. We want to study their relative propensity to marry up.

Let the local log odds $l_{B,e_m,(B,W),e_f}$ denote

$$l_{B,e_m,(B,W),e_f} = \ln\left[\frac{\mu_{B,e_m}+1,W,e_f}{\mu_{B,e_m,W,e_f}}\right]\left[\frac{\mu_{B,e_m}+1,B,e_f}{\mu_{B,e_m,B,e_f}}\right]^{-1} = \ln\frac{D}{C} \quad [8]$$

D is the ratio of the number of White women who married $e_m + 1$ Black men relative to the number marrying e_m Black men. C is the ratio of the number of Black women who married $e_m + 1$ Black men relative to the number marrying e_m Black men. If $D > C$, then White women with education e_f have a larger log odds of marrying $e_m + 1$ Black men to e_m Black men than Black women with the same education. The local log odd $l_{B,e_m,(B,W),e_f} > 0$ consistent with social exchange in marriage between Black men and White women. If $l_{B,e_m,(B,W),e_f} = 0$, there is random matching between these two types of husbands and wives. With four educational level for each gender, there are $(E_m - 1) \times E_f = 3 \times 4 = 12$ of these local log odds ratios.

Table 5 shows the values of these 12 local log odds ratios.

Let $m_{B,(e_m e_{m+1}),(BW),e_f}$ be the number of Black men with education e_m or e_{m+1} who are married to Black or White women

Table 4 Ethnic and education marital matching in the U.S. 2000 census

		Female							
		White				Black			
Male		LHS	HS	LBA	BA	LHS	HS	LBA	BA
White	LHS	2624	3411	1971	441	5	6	9	2

	HS	25	99	51	16	291	1533	1134	282
	LBA	18	79	167	77	161	623	1880	760
	BA	4	11	59	126	30	141	491	1063

LHS, less than high school; HS, high school graduate; LBA, some college; BA, BA or more.

Table 5 Local log odds for B men with e_m or e_m+1 married to W and B women with e_f

	Female			
Black male	*W_LHS\B_LHS*	*W_HS\B_HS*	*W_LBA\B_LBA*	*W_BA\B_BA*
LHS\HS	0.84	0.11	−0.29	0.34
HS\LBA	0.26	0.67	0.68	0.58
LBA\BA	0.18	−0.49	0.30	0.16

LHS, less than high school; HS, high school graduate; LBA, some college; BA, BA or more.

of education e_f. We compute both unweighted and population-weighted fraction of strictly positive local log odds to get indices for the propensity of White women to intermarry racially in order to marry a more educated spouse:

$$X_{B,e_m,(B,W),e_f} = \sum_{e_m=1}^{E_m-1}\sum_{e_f=1}^{E_f}\frac{\Phi\left(l_{B,e_m,(B,W),e_f}\right)}{(E_m-1)\times E_f} \quad [9]$$

$$X^W_{B,e_m,(B,W),e_f} = \sum_{e_m=1}^{E_m-1}\sum_{e_f=1}^{E_f}\left[\frac{\ln m_{B,(e_m,e_{m+1}),(BW),e_f}}{\sum_{h=1}^{E_m-1}\sum_{g=1}^{E_f}\ln m_{B,(h,h+1),(BW),g}}\right]\Phi\left(l_{B,e_m,(B,W),e_f}\right)$$

If the indices are larger than 0.5, then the society exhibits social exchange in marriage in the sense defined above. The indices are bounded above by 1 and bounded below by zero. Based on data in Tables 4 and 5, $X_{B,e_m,(B,W),e_f} = 0.83$ and $X^W_{B,e_m,(B,W),e_f} = 0.83$. So there is empirical support for social exchange in marriage between White women and Black men.

What about social exchange in marriage between Black women and White men? Consider Black women with education e_f or e_f+1 and White and Black men with education e_m. Both Black and White men have the same level of education. We want to study their relative propensity to marry up.

Interchanging genders in the definition of the local log odds in eqn [8], Table 6 shows the values of the 12 local log odds ratios $l_{B,e_f,(B,W),e_m}$.

Similarly, based on data in Tables 4 and 6, $X^F_{B,e_f,(B,W),e_m} = 0.58$ and $X^{W\,F}_{B,e_f,(B,W),e_m} = 0.59$. As discussed earlier, if there is no social exchange, we expect the value of the index to be 0.5. Thus $X^F_{B,e_f,(B,W),e_m} = 0.58$ and $X^{W\,F}_{B,e_f,(B,W),e_m} = 0.59$ show that there is minimal social exchange in marriage between White men and Black women. Our findings, (1) that there is social exchange in marriage between White women and Black men, and (2) there is minimal social exchange in marriage between White men and Black women replicate the conclusions in Gullickson and Fu (2010).

Table 6 Local log odds for B women with e_f or e_f +1 married to B or W men with e_m

	Female		
Male	*LHS\HS*	*HS\LBA*	*LBA\BA*
W_LHS\B_LHS	0.24	0.59	−0.05
W_HS\B_HS	−0.09	0.65	−0.06
W_LBA\B_LBA	0.44	−0.44	0.09
W_BA\B_BA	−0.74	0.05	0.10

LHS, less than high school; HS, high school graduate; LBA, some college; BA, BA or more.

Finally, in all the three studies of ethnic endogamy, PAM, and social exchange, the values of the unweighted versus population-weighted indices measuring a particular marriage matching pattern were quantitatively similar. So in these cases, there is little gain to compilation weighted indices. The simpler unweighted indices sufficed.

A Behavioral Interpretation of Local Log Odds in Marriage Matching

When there are more marriages of (i, j) couples than marriages of (h, k) couples, analysts often infer that (i, j) couples must be more attracted to each other than (h, k) couples. There are three related concerns with such an inference. First, there may be more h and k individuals in the population than i and j individuals. In other words, we need to control for differences in population supplies. Second, is 'more attracted to' a statement about preferences for different types of spouses or is it a combination of spousal preferences plus resource allocations within those marriages. For example, young women who marry older rich men may prefer to marry younger men but the older men can provide more resources to their young wives. Third, can we learn anything about male versus female preferences from observing marital matching patterns?

This section applies Siow which uses the CS model to provide a behavioral interpretation of local log odds in marriage matching which also deals with the three concerns raised above (Siow and CS have been further characterized and extended in several directions (e.g., Decker et al., 2013; Galichon and Salanie, 2012; Graham, 2011)). The CS model belongs to the class of frictionless transferable utility marriage models which was introduced by Becker (1973; reprinted 1991) to bring demand and supply analysis to marriage markets.

Consider a marriage market where there are I types of men, $i = 1, \ldots, I$, and J types of women, $j = 1, \ldots, J$. M is a population vector where an element m_i is the number of eligible (single) men of type i. F is a population vector where an element f_j is the number of eligible (single) women of type j. μ_{ij} is the number of marriages between type i men and type j women. μ_{i0} and μ_{0j} are the number of type i and type j women, respectively, who remains unmarried.

Each marital match between two different types of individuals constitutes a distinct submarriage market. With I types of men and J types of women, there are $I \times J$ submarriage markets.

Let the systematic marital output of a type i man married to the type j woman be π_{ij} which is divided between the two spouses.

Let $\tilde{\tau}_{ij}$ be the share of the systematic marital output that is obtained by a type j wife. Each wife also gets an idiosyncratic payoff from marriage which depends on her specific identity, the type of spouse that she marries and not his specific identity. Her idiosyncratic payoff also does not depend on $\tilde{\tau}_{ij}$.

In an (i, j) marriage, $\pi_{ij} - \tilde{\tau}_{ij}$ is the share of systematic marital output that is obtained by a type i husband. Each

husband also gets an idiosyncratic payoff that is specific to him, the type of spouse that he marries and not her specific identity. His idiosyncratic payoff also does not depend on $\pi_{ij} - \tilde{\tau}_{ij}$.

The above assumptions imply that every type i male regards every type j female as perfect spousal substitutes and vice versa.

Each individual also gets a systematic payoff from remaining unmarried which depends on their type, π_{i0} and π_{0j} for the type i man and type j woman, respectively, as well as an idiosyncratic payoff which depends on their specific identity.

Given their payoffs, both systematic and idiosyncratic, from every potential spousal choice including remaining unmarried, each individual will choose the spousal choice which maximizes their utility.

The roles of systematic versus idiosyncratic payoffs are as follows. Consider two types of men, i and i', that a type j woman may marry. If the systematic share $\tilde{\tau}_{ij}$ exceeds $\tilde{\tau}_{i'j}$, then all other things equal, type j women will prefer to marry type i men rather than type i' men. With the addition of idiosyncratic payoffs, a particular type j woman may get a very large idiosyncratic payoff from marrying a type i' man compared with her idiosyncratic payoff from marrying a type i man and so choose to marry the type i' man in spite of the unfavorable difference in systematic payoffs. So the difference in systematic payoffs captures the observation that type j women are more likely to marry type i men than type i' men. The idiosyncratic payoffs allow some (i', j) marriages.

We aggregate these individual decisions into demand and supply functions for spouses in every (i, j) submarriage market. For a given transfer, $\tilde{\tau}_{ij}$, the demand by type i men for type j wives may not equal the supply of type j women for type i husbands. If the demand for wives exceeds the supply, $\tilde{\tau}_{ij}$ will rise and vice versa.

The marriage market clears with equilibrium transfers $\tilde{\tau}_{ij} = \tau_{ij}$, when the number of type i men who want to marry type j women will be exactly equal to the number of type j women who want to marry type i men for all (i, j) submarriage markets. In marriage market equilibrium, every individual chooses the type of spouse they want to marry or chooses to remain unmarried.

Using a particular formulation for systematic and idiosyncratic payoffs, McFadden's (1974) additive random utility model, for modeling spousal choice, CS showed that for every (i, j):

$$\ln \frac{\mu_{ij}}{\sqrt{\mu_{i0}\mu_{0j}}} = \frac{\mu_{ij}}{\sqrt{\left(m_i - \sum_k \mu_{ik}\right)\left(f_j - \sum_h \mu_{hj}\right)}} \qquad [10]$$

$$= \frac{\pi_{ij} - \left(\pi_{i0} + \pi_{0j}\right)}{2} \qquad [11]$$

The left-hand side of eqn [10] is observed by the analyst. It is the log of the number of (i, j) marriages divided by the geometric mean of the number of unmarried type i men and unmarried type j women. CS calls the left-hand side of eqn [10] the total gains to marriage. The right-hand side of [11] provides a behavioral interpretation of the total gains to marriage. It is the per spouse systematic payoff to type i man marrying a type j woman minus the systematic payoffs to them remaining unmarried. See CS for an application to changes in the U.S. marriage market induced by the legalization of abortion; Brandt et al. (2008) for estimating the marital outcome of children born during the 1960 famine in rural China; Bruze et al. (in press) on marriage, divorce, and remarriage in Denmark; Chiappori et al. on the evolution of marriage matching by educational attainment in the US (2011).

There are three important points about eqn [10]. First, equilibrium transfers or the equilibrium division of resources between spouses, τ_{ij}, do not appear in [10]. Thus the total gains to marriage do not provide any information on within household allocations between spouses. Second, variations in populations of different type of individuals affect equilibrium transfers but do not affect the total gains to marriage. Third, the total gains to marriage do not provide any information on who, the husband or wife, contributes more to the marriage.

Apply eqn [10] to marriages between men of types i and i' and women of types j and j';

$$\ln \frac{\mu_{ij}\mu_{i'j'}}{\mu_{ij'}\mu_{i'j}} = \ln \frac{\mu_{ij}}{\sqrt{\mu_{i0}\mu_{0j}}} + \ln \frac{\mu_{i'j'}}{\sqrt{\mu_{i'0}\mu_{0j'}}} - \ln \frac{\mu_{ij'}}{\sqrt{\mu_{i0}\mu_{0j'}}} - \ln \frac{\mu_{i'j}}{\sqrt{\mu_{i'0}\mu_{0j}}} \qquad [12]$$

$$= \frac{1}{2}\left(\pi_{ij} + \pi_{i'j'} - \pi_{ij'} - \pi_{i'j}\right) \qquad [13]$$

The left-hand side of eqn [12] is a local log odds of this marriage market. It is observed by the analyst. Equation [13] provides an interpretation of the local log odds in terms of the marital output function, π_{ij}. We will use it to interpret the various local log odds which were discussed earlier.

Rationalizing Endogamy

Let $i = j = W$ and $i' = j' = B$, then eqn [12] becomes

$$l(W, B) = \ln\left[\frac{\mu_{WW}\mu_{BB}}{\mu_{WB}\mu_{BW}}\right] = \frac{1}{2}\left(\pi_{WW} + \pi_{BB} - \pi_{WB} - \pi_{BW}\right) \qquad [14]$$

The local log odd in eqn [14] is the same as that in eqn [1], the local log odd for Black and White marriages. The right-hand side of [14] provides a behavioral interpretation of the local log odd. The right-hand side is positive when the sum of marital outputs from own race marriages exceeds the sum of marital outputs from mixed race marriages. The right-hand side is negative when the sum of marital outputs from own race marriages is less than the sum of marital outputs from mixed race marriages. The right-hand side is equal to zero when the sum of marital outputs from own race marriages is equal to the sum of marital outputs from mixed race marriages.

When $l(W, B) > 0$, CS rationalizes endogamy by saying that the sum of marital outputs from own race marriages is less than the sum of marital outputs from mixed race marriages. Sociologists and demographers interpret local log odds and related statistics as quantifying 'forces of attraction' in marriage. Some economists have worried about the 'force of attraction' interpretation of local log odds because supply considerations are not present, i.e., the number of Blacks and Whites do not appear in $l(B, W)$. CS provides a formal rationalization for 'forces of attraction' interpretation. Moreover, CS derives the interpretation of the local log odds from a model of marriage

market equilibrium which explicitly takes supply considerations into account.

Rationalizing PAM

Now let men and women be differentiated along one dimension of ability which is educational attainment. So with I types of men, let the education of a type i man be i. So the educational attainment of a type i man is lower than that of a type $i+1$ man. And similarly with J types of women, let the educational attainment of a type j woman be j.

Let $i' = i+1$ and $j' = j+1$. Then eqn [12] becomes

$$l(i,j) = \ln\left[\frac{\mu_{ij}\mu_{i+1,j+1}}{\mu_{i,j+1}\mu_{i+1,j}}\right] = \frac{1}{2}\left(\pi_{ij} + \pi_{i+1,j+1} - \pi_{i,j+1} - \pi_{i+1,j}\right) \quad [15]$$

When the marital output function is π_{ij} supermodular, i.e., the right-hand side of eqn [15] is strictly positive, then the local log odds $l(i, j)$ is positive. Put another way, $l(i, j) > 0$ implies that the sum of marital outputs by PAM is larger than the sum of marital outputs by negative assortative matching. Siow was the first to discover this result. Graham provides the most general version of this result to date. These results are the stochastic generalization of Becker's famous deterministic PAM matching result where he showed that if the marital output function is supermodular, there will be strict PAM in marriage. The stochastic generalizations are empirically useful because strict PAM is never observed.

Note again that population supplies do not directly affect eqn [12]. Thus analysts who want to study PAM using log-linear models and local log odds models do not have to worry about population supplies.

Rationalizing Trade-Offs in Multidimensional Matching

Now let men and women be differentiated by race and educational attainment. Let a type i man be a Black man with $e_m + 1$ amount of education. Let a type i' man be a Black man with e_m amount of education. Let a type j woman be a White woman with e_f amount of education. Let a type j' woman be a Black woman with e_f amount of education. Then eqn [12] becomes

$$l_{B,e_m,(B,W),e_f} = \ln\left[\frac{\mu_{B,e_m+1,W,e_f}}{\mu_{B,e_m,W,e_f}}\right]\left[\frac{\mu_{B,e_m+1,B,e_f}}{\mu_{B,e_m,B,e_f}}\right]^{-1} \quad [16]$$

$$= \pi_{B,e_m+1,W,e_f} - \pi_{B,e_m+1,B,e_f} - \left(\pi_{B,e_m,W,e_f} - \pi_{B,e_m,B,e_f}\right) \quad [17]$$

$l_{B,em,(B,W),ef}$ in eqn [16] is the same as that in eqn [8]. So there will be social exchange in marriage between Black men and White women when the difference in marital outputs of between White and Black wives with Black husbands with $e_m + 1$ schooling is larger than the difference in marital outputs between White and Black wives with Black husbands with e_m schooling.

Conditional PAM

Most empirical research on spousal matching by educational attainment condition on other spousal characteristics. For example, this article conditioned on age and ethnicity. Marital outputs are affected by these other characteristics. This subsection will show that the above results apply conditional on other spousal characteristics.

Together with i, let there be K, $k = 1, \ldots, K$ other characteristics which defines a type of male in the marriage market. k may be a White male between ages 32 and 36. Thus a type of male is now indexed by (i, k). There are $I \times K$ types of men on the society. Together with j, let there be L, $l = 1, \ldots, L$ other characteristics which define a type of female in the marriage market. l may be a White female between ages 31 and 35. Thus a type of female is now indexed by (j, l). There are $J \times L$ types of women on the society.

Consider the CS model where the systematic marital output of an $(i, k) \times (j, l)$ marriage is denoted as $\pi_{(i,k),(j,l)}$. The additive idiosyncratic payoff an individual to any spousal choice is as before. Marital transfers are used to clear the $I \times K \times J \times L$ marriage markets simultaneously. Then Siow shows

$$\ln\frac{\mu_{(i,k),(j,l)}}{\sqrt{\mu_{(i,k),0}\mu_{0,(j,l)}}} = \frac{\pi_{(i,k),(j,l)} - \pi_{(i,k),0} - \pi_{0,(j,l)}}{2} \forall (i,k),(j,l)$$

Conditioning on k and l, we obtain the conditional local log odds:

$$\ln\frac{\mu_{(i+1,k),(j+1,l)}\mu_{(i,k),(j,l)}}{\mu_{(i,k),(j+1,l)}\mu_{(i+1,k),(j,l)}}$$

$$= \pi_{(i+1,k),(j+1,l)} + \pi_{(i,k),(j,l)} - \left[\pi_{(i,k),(j+1,l)} + \pi_{(i+1,k),(j,l)}\right]$$

All the previous results in the above subsections apply conditional on k and l. For example, conditional on k and l, if the marital output function $\pi_{(i,k),(j,i)}$ is supermodular in i and j, the conditional spousal educational matching distribution is $TP2$. Thus CS rationalizes the standard practice of studying spousal educational matching conditional on other spousal characteristics as is also done here.

Asylum Seekers

Linda Briskman, Swinburne University of Technology, Melbourne, VIC, Australia

Abstract

The treatment of asylum seekers in the modern nation-state violates human right norms. Exclusion from nation, an emphasis on border protection, and the use of immigration detention facilities are among the approaches aimed at deterring people from seeking safe haven. Many of these practices are antithetical to social work ethics and values, and social work practitioners can use their practice wisdom and advocacy skills to promote alternatives to current policies and practices.

Introduction

The rights of asylum seekers are one of the most publicized and politicized public policy issues. This article outlines the global context of asylum seeking and border control and highlights the distinguishing features of the modern nation-state response, including immigration detention. The question of racialized policies is in the forefront. Attention is also given to the role of social work, and suggestions are made for ways forward for more humane approaches that cohere with human rights norms.

Background

The terms asylum seeker and refugee are often confused. An asylum seeker is a person who says that he or she is a refugee, but whose claim has not yet been assessed. A refugee has been assessed by a government or by the United Nations High Commissioner for Refugees (UNHCR) as set out in the 1951 Convention Relating to the Status of Refugees, commonly known as the Refugee Convention (AHRC, 2012). Countries that have ratified the Convention are obliged to assess asylum seekers' claims for protection.

According to the Refugee Convention, a refugee is a person who is outside his or her own country and is unable to return due to a well-founded fear of persecution on the following grounds: race, religion, nationality, membership of a particular social group or political opinion (UNHCR, 1951). More than 140 countries have acceded to the 1951 Convention or its 1967 Protocol, and many of these countries have incorporated the refugee definition of the Convention within national legislation (UNHCR, 2007).

In this article, the terms asylum seeker and refugee are occasionally used interchangeably to denote shared experiences and reflect the literature.

There are approximately 15.2 million refugees in the world (RCOA, n.d.). The 20 nations with the highest number of refugees are all developing countries, including 12 least developed countries, with more than 42% of the world's refugees residing in nations where gross domestic product per capita is below US$3000 (UNHCR, 2010).

The top three countries of origin of refugees under UNHCR's mandate are Afghanistan, Iraq, and Somalia (RCOA, 2010). The top refugee host countries include Pakistan and Iran, both non-Western countries. Pakistan hosts 2 million refugees, the United Kingdom around 238 000, and Australia approximately 22 000 (RCOA, 2010). In terms of resettlement of refugees, the top three countries are the United States, Canada, and Australia (RCOA, 2010). Resettlement opportunities are extremely limited; in 2009, a mere 1% of the world's refugees were resettled and estimates are that it would take 188 years for the world's refugees to be resettled (RCOA, n.d.). Formal protection spaces are shrinking and many people are in protracted refugee situations. A protracted refugee situation is defined as one in which refugees have been in exile for more than 5 years and for whom solutions are not evident in the foreseeable future (Loescher and Milner, 2009).

As signatories to the Refugee Convention harden their entry stance, restrictions imposed have the effect of encouraging refugees to engage people smugglers to assist them in crossing borders, often in a dangerous manner. Between 1993 and 2010, nearly 14 000 people are known to have died trying to enter Europe, while in detention, or during forcible deportations (Weber and Pickering, 2011). The causes of deaths vary according to context, but include drowning during boat journeys, suffocation in lorries or containers, vehicle accidents, suicides, and environmental exposure in deserts (Weber and Pickering, 2011).

Border Security vs Human Security

A preoccupation exists with the sanctity of nation-state borders, which is privileged over the security of people. As border security measures increase, the security of people in many countries is threatened by what are known as push factors, which propel movement to countries perceived to be safe. Lester (2010) argues that the breakdown in the human security of people has a ripple effect that transcends borders. Factors such as conflict, inequality, human rights abuses, terrorism, environmental degradation, and transnational organized crime are not isolated events. Yet, asylum seekers are cast as agents of human insecurity, which is evident in the xenophobic responses of host states (Lester, 2010), and can have devastating consequences for the fleeing asylum seeker.

Many asylum seekers have experienced torture and trauma and the provision of casework services to this group is often the point of entry for social workers. Survivors of torture may experience chronic symptoms that continue for many years

 http://dx.doi.org/10.1016/B978-0-08-097086-8.28008-2

including hyperarousal, sleep problems, irritability, poor memory and concentration, reexperiencing traumatic events, and social withdrawal (Bowles, 2005). The experience of torture and trauma regrettably does not activate a welcoming response for asylum seekers for, as Edwards and Ferstman (2010) argue, rather than being viewed as people exercising their rights to seek asylum, as enshrined in international law, they are denoted as invaders. This means that as noncitizens they are dealt with by discrimination, xenophobia, and criminalization. Grewcock (2009) says that criminalizing people for a legal activity results in people being treated like criminals through naval interception, maximum security prisons, the employment of guards, and the use of physical constraints and weaponry. This compounds the trauma already experienced.

Attempts to eliminate the people smuggling trade are the cornerstone of border protection. Alison Mountz (2010) notes that human smuggling is in many ways routine and a historical phenomenon that has existed for centuries. Among accounts of the need for human smugglers are those who used such services to flee the Nazi Holocaust. Those who assisted them, such as Oskar Schindler, are now portrayed as heroic. In popular discourses, however, smugglers are portrayed as enemies of the state.

Racism

It is not possible to critique the manner in which asylum seekers are treated without examining questions of racism, a construct that is familiar to social workers through antiracist theorizing. Institutional racism takes forms that are ingrained in practices that privilege dominant paradigms. Since the attacks in the United States on 11 September 2001, Muslims, including Muslim asylum seekers, have been depicted as terrorists who are seen as intent on changing societal ways of life and unappreciative of Western values. The so-called war on terror since 2001 has ushered in new state racism through laws, administrative edicts, and judicial systems that shape popular racism (Sivandan, 2007). By conflating asylum seeking with terrorism, nation-states have been able to introduce harsh measures that are supported by their constituents. When fear is injected into the populace about those depicted as 'the threatening other', there is acceptance of inhumanity to vulnerable people who are seeking help.

Asylum policies can disproportionately penalize people who are not legal citizens of a nation. Asylum seekers can be punished merely because they cross borders without documentation to seek asylum as enshrined in international norms. The Canadian group 'No-One is Illegal' argues that granting citizenship to a privileged few represents racist immigration and border policies aimed at exploiting and marginalizing migrants (NOI, n.d.).

Racism and xenophobia are not caused by isolated acts of individuals. Rather, racism expressed at the individual level is representative of "an orchestrated effort by segments of the dominant society to wage a war on the poor and on people who, by virtue of their race, ethnicity, language, and class are reduced at best to half-citizens and at worst to a national enemy responsible for all the ills afflicting our society" (Macedo and Bartolome, 2001: p. 6). Institutionally, the way race thinking materializes is evident in the field of migration, where nations are increasingly putting up their shutters to keep out people who are seen not only as a potential terrorist threat but also as undermining the nation's demographic order and the value base of society. This results in insidious assimilation approaches that require people to relinquish their identities to fit into the dominant society. This is antithetical to social work principles and constructs of cultural diversity and antiracism. In the new world order, assimilation ideologies fuse with security discourses. These security discourses provide the rationale for racialized immigration policies (Burke, 2001). In addition, asylum seekers and refugees are rarely accorded a voice of their own and they are:

> Typically a two-dimensional character, a blank screen upon which other's agendas and narratives can be projected. The actions of refugees are narrated for the general public of the Global North by charities, refugee advocates, health professionals, politicians and others.
>
> (Fiske, 2012: p. 17)

Moreover, the perceptions of asylum seekers and refugees are often mediated by sections of the media, which defy their own codes of ethics by using language that demonizes asylum seekers and colludes with governments, directly and indirectly, to invoke fear.

The Use of Immigration Detention

Immigration detention is one of the starkest illustrations of the tough manner in which asylum seekers are treated. Detention deprives people of liberty and such deprivation is one of the most serious sanctions a state can issue against a person and in other circumstances is normally proscribed except when authorized by a court (Briskman et al., 2008). The Geneva-based Global Detention Project (GDP) (n.d.) explains the use of detention as the practice of detaining on administrative (as opposed to criminal) grounds. The GDP states that because many national legal systems do not have clear rules for such detention, those detained face legal uncertainties, including the absence of limitations on the duration of their detention.

The detention of people deemed unauthorized has grown enormously in scope and scale in the past 30 years and many developed nations hold unauthorized or rejected foreigners in prisonlike facilities (Wilsher, 2012). This is nowhere clearer than in the case of asylum seekers who can often be held in an arbitrary manner and for extended periods, outside the mainstream of the law, in inhumane conditions (Wilsher, 2012). Although the UNHCR guidelines on detention (UNHCR, 2012) specifically prohibit detention for the purposes of deterrence as such policies are generally unlawful under international law, this practice is increasing. The privatization of detention is also a common feature whereby more than a dozen countries have employed private contractors in some form within their immigration detention institutions (Flynn and Cannon, 2009).

Australia has one of the harshest detention regimes in the world and is a country illustration of how stridently this

provision is implemented especially as, on a global scale, it receives a relatively low number of asylum seeker arrivals. Since 1992, legislation has been in place to detain mandatorily people arriving without authorization. Mandatory detention is mostly applied to asylum seeker boat arrivals and frequently takes place in remote and island locations, including in the nations of Nauru and Papua New Guinea.

Detention in Australia applies to men, women, and children. Two Australian social work academics describe the practice of detaining children as 'organized and ritualized abuse' by the Australian government (Goddard and Briskman, 2004: p. 17). As of February 2014 approximately 1000 children were held in closed immigration detention (AHRC, 2014), prompting the announcement of an official inquiry by the Australian Human Rights Commission into child detention. At the same date, around 116 children are believed to be held in Nauru detention facilities (Chilout, 2014).

The detention of children occurs in other nations. A survey of 21 countries found that there is an increasing trend to detain migrant, asylum seeker, and refugee children (IDC, 2012a). The IDC (2012b) explains that such detention has negative physical, psychological, and emotional impacts.

In the United Kingdom although fewer children are being detained than under the previous government, the number of children held in what is known as predeparture facilities is increasing (End Child Detention Now, 2012). Furthermore, a report by the Refugee Council in the United Kingdom accuses the immigration service of detaining child asylum seekers by wrongly classifying them as adults (McVeigh, 2012). Human Rights Watch (2012) in criticizing proposed legislation in Canada speaks of the violation of human rights law by allowing for a year of detention without review for certain groups of people, including 16- and 17-year old children (Human Rights Watch, 2012).

There are alternatives to detention in place in some contexts. According to the International Detention Coalition (IDC) (2012b), countries such as Belgium have alternatives to immigration detention for children and countries like Japan, Holland, and the United Kingdom have recently taken steps to release children or to prevent totally their detention. In Australia, under the Labor government, which was voted out of office in September 2013, there was increasing use of community options during claims processing. However, 1765 children are in situations where their parents have no work rights and limited access to government support (ChilOut, 2014). Social workers are among those who have been employed in programs contracted to nongovernment organizations that provide support to asylum seekers in the community. The emphasis on the change to a Coalition government is now on a policy named Operation Sovereign Borders that gives priority to turning back boats to Indonesia and reducing the number of arrivals to Australia. Clearly, there is no place for social workers in militiarized responses.

Islands as Places of Banishment

A disturbing trend is the use of islands for immigration detention purposes. Holding people on islands makes them more difficult to access and more detached from advocates, lawyers, and other services. Mountz and Briskman (2012) note:

> At the unaccountable border, nation-states can exercise their power with impunity and brutality. In these sites of exclusion, liberty is denied and normative state rights minimised. Identity is discounted and the demonised, criminalised asylum seeker is uncritically perceived by those far away from the island in the nation's heartland as a threat to the nation, creating panic and fear.
>
> (Mountz and Briskman, 2012: p. 23)

The islands of Guam and Saipan, Lampedusa, Christmas Island, and Guantanamo Bay are cases in point. These islands are linguistically, culturally, economically, geographically, and jurisdictionally different from one another. In each region, however, these islands feature in struggles over migration and each island has a history of crisis surrounding marine arrivals (Coddington et al., 2012).

As an archipelago of small Pacific Islands under US jurisdiction, Guam and the Commonwealth of Northern Mariana Islands are geographically remote from, and geopolitically significant to, the United States. Guam and Saipan are apparent in US endeavors to manage and restrict asylum-based immigration (Coddington et al., 2012). Immigration detention facilities are located at the US naval station on Guantanamo Bay; the use of Guantanamo for this purpose is not generally known (Dastyari and Effeney, 2012). The Italian island of Lampedusa has been a significant point of arrival for migrants and refugees from North Africa where they are detained in such substandard conditions that it has been reported that the European Commission may initiate legal action (CBC News, 2013).

Christmas Island, an Indian Ocean Territory of Australia, is a site of detention containment. Until the change to a Coalition government in 2013 and the subsequent Operation Sovereign Borders policy, boat arrivals usually reached Christmas Island from the transit destination of Indonesia. Nearly all were detained on Christmas Island for initial processing before being transferred to the mainland, with adult men usually held in a maximum security facility. Now asylum seekers who have made their way to Christmas Island are held there while awaiting transfer to Nauru or Manus Island (Papua New Guinea).

The Role of Social Workers

Although there are internationally agreed definitions and standards about social work, as Banks (2012) notes how social work is practiced in different countries is linked to context including national and regional welfare regimes, social welfare laws and policies, the roles of the state, as well as market and not-for-profit organizations. There is also an imperative to think beyond the local to international forms of social work (Ife, 2001) and as discussed below, social workers need to traverse the global and the local in considering their roles and responses to situations.

The involvement of social workers with asylum seekers has not been surveyed on an international basis. Collett's (2004: p. 84) observation in the United Kingdom that "asylum seekers

are still not regarded as significant enough to be a focus of social work training" is mirrored in other countries.

Collett (2004) refers to the gatekeeping role of social workers in the United Kingdom. Rather than viewing asylum seekers as clients, they can be drawn into informing on behalf of immigration services. This characteristic has been subject to robust debates within social work of how social control ideologies have characterized appraisals of professionalism, particularly where practitioners may be expected to provide the contradictory roles of care agent and control agent (Briskman et al., 2012). Social work has been criticized for the attention given to the management of social problems on behalf of governments. Although conceptions of abuse have widened to include institutional abuse (Cemlyn and Briskman, 2003), social workers can inadvertently become partners in implementing repressive approaches that are masked as providing caring services. The activities of the profession in the United Kingdom with regard to asylum seekers tend to be derived from values concerned with investigation, rationing, gatekeeping, and surveillance. These are separated from ethics, sensitivity, accountability, and empathy (Humphries, 2004). Although not often expressed in the social work literature, dual loyalty is an explanatory framework.

Dual loyalty issues arise where the loyalty of a health or welfare professional to patient or client is compromised by obligation to the employing body, which may represent the interests of the state. Historically, the ethical obligations of health and welfare professionals have privileged the need for loyalty to patients and clients (Briskman et al., 2012), but these boundaries may be crossed with asylum seekers.

An examination of research conducted with nurses who worked in immigration detention in Australia sheds light on the conflict that besets those who conduct human services work in closed environments. Deborah Zion et al. (2009) interviewed a sample of nurses who had worked on the frontline of health care in immigration detention services. Although nurses were ascribed responsibility and power, it was limited to enforcing the rules set out by the private detention providers and immigration department. Against the odds, many focused on the ethics of nursing to enact a duty of care and display empathy, but this could not compensate for the inhuman conditions in which asylum seekers found themselves. This would have required political action (Zion et al., 2009: p. 550).

Social workers and other human services professionals can be compromised in their work, particularly if they are silenced through contracts of confidentiality and limits to speaking out. Gready's (2007) analysis of medical complicity in human rights abuses in apartheid South Africa resonates. He argues (p. 417) that it is difficult to draw the line between active and passive collaboration, referring to 'moral disengagement'.

Humphries (2004) provides some directives for social workers, arguing that social work is not inevitably an arm of oppression and the profession has a choice to make a new moral effort to engage its knowledge about sources of inequality with a sense of urgency. Asylum seekers, says Humphries, are a dramatic example of people regarded as undeserving, worthy of derision, abysmal treatment, and expulsion.

An International Human Rights Approach

Human rights social work academic Jim Ife (2001) laments the way in which social problems are often framed as national problems, with little acknowledgment of shared global problems, global causes, and global solutions. Khan and Dominelli (2000) refer to how globalization contributes to the internationalization of social problems, with some social workers facing issues that transcend national boundaries including asylum migration. Ife concurs, noting that with refugees and asylum seekers, an issue so obviously global and internationally linked, the response by activists is often confined to national perspectives seen as 'Canada's refugee problem', 'Australia's treatment of illegal immigrants', or 'the need for Kosovo to be made safe again' (Ife, 2001: p. 74). He argues for all of social work to be concerned with the global and all social work in this sense is international social work. Similarly, Phillippe Legrain (2006) says that focusing on individual nation-states provides a distorted and partial view, for the increase in international migration is not occurring in a vacuum but is part of a globalization process.

The Universal Declaration of Human Rights (United Nations, 1948) is a starting point for fair treatment. It states that all people have the right to seek and to enjoy in other countries asylum from persecution. It also states that all people have the right to work, that no one should be subjected to arbitrary detention; cruel, inhuman, or degrading treatment; or interference in their family unit. All these provisions are breached by many nation-states. It should serve as a reminder to violating nation-states and their supporters that at the end of the Second World War the Declaration was designed to guarantee the rights of every individual and to uphold dignity and justice for all. More than 50 states participated in its drafting. Apart from the Refugee Convention of 1951, other relevant instruments that signed-up nation-states need to be cognizant about in their treatment of asylum seekers are the Convention against Torture and the Convention on the Rights of the Child.

To develop clarity about their positions, a human rights approach provides a basis for assertive practice in confronting violations (Briskman and Cemlyn, 2005). A human rights social work approach ought be a political endeavor. Furthermore:

> Social workers with a commitment to anti-oppressive and anti-racist philosophies should inform themselves of the local context, in order to challenge stereotypes of racism. They have a role in counteracting the dehumanisation of asylum seekers and educating the wider community.
>
> (Briskman and Cemlyn, 2005: p. 721)

Advocacy and Social Work: Prospects and Limits

While harsh policies are meted out to asylum seekers, there have been concerted endeavors to protest against and reverse dominant discourses and inhumane practices. These are evident in social movements in a number of countries whereby organizations and individuals form collectives to proffer alternatives to cruel regimes and to expose the injustices. In their contest with the state, social movement actors may be discounted in

dominant narratives of nationhood and nation building that are portrayed by the state (Wills, 2009). Nonetheless, those involved in social movements provide a humanizing ethic of how those discarded by the nation-state can be treated in a responsible manner (Stratton and McCann, 2002). It is unknown how many social workers have been involved in such movements either professionally or individually; however, there are some documented examples including the social work-inspired People's Inquiry into Detention described below.

Among the groups that have coalesced for the rights of asylum seekers, refugees, and undocumented migrants are those on the US-Mexico border, and sanctuary movements based around church organizations to provide protection for people facing deportation (Gosden, 2012). Australia has a long history of asylum seeker activism with the common aim of ending mandatory detention. In the United Kingdom, a large antidetention lobby exists that ranges from exposing detention practices, particularly in the medical sphere, to organizing campaigns for the release of children. In Canada, the 'No-One is Illegal' group fights for the rights of all migrants to live with dignity and respect.

Global organizations also exist including the IDC that has 250 members working in 50 countries to undertake research, advocate, and provide direct services to and on behalf of refugees, asylum seekers, and migrants (IDC, n.d.). The GDP is an interdisciplinary research endeavor that investigates the role detention plays in states' responses to global migration (Global Detention Project, n.d.).

Social workers can form alliances at local, regional, and international levels to promote policies and practices that address fundamental injustices. Doing so requires a review of the knowledge and skills needed and the approaches that are relevant (Lyons et al., 2006). Social workers are among those who have joined movements to bring about change and provide support to asylum seekers. They are among the membership of refugee action collectives, are in touch with legal representatives, join in demonstrations, and visit detention centers (Cemlyn and Briskman, 2003).

Social work ethics guide action. Wherever in the world social workers practice, they deal with ethical challenges about how to treat and respond to people respectfully and whether and how to resist, ameliorate, or tolerate the social injustices they see on a daily basis (Banks, 2012). There are directives and principles enshrined in social work ethics, national and international, which call upon social workers to affirm human rights and to challenge unjust principles. The International Statement of Ethical Principles proclaims that the principles of human rights and social justice are fundamental to social work (IASSW and IFSW, 2004).

Apart from codified ethics, the practice wisdom of social workers can facilitate action. Social workers are witness to the impact of subjugation, oppression, racism, and structural disadvantage. By applying theories of anti-oppressive practice, and a human rights framework to analyzing policies on the ground, an emancipatory outlook can be adopted that challenges and questions the harms done to vulnerable people. Social work educators have an important role.

One Australian example of social workers enacting their moral responsibility was an initiative undertaken under the auspices of the Australian Council of Heads of Schools of Social Work (ACHSSW). From 2005 to 2008, the ACHSSW facilitated a People's Inquiry into Detention to expose and influence the harmful policies that breached core human rights tenets. The ACHSSW had no authority to enact such a project except the authority of 'the people' and a commitment to give voice to the voiceless who were incarcerated in Australia's detention centers (Briskman et al., 2008).

There are risks attached to advocacy endeavors including when initiated by social work educators. One only has to contemplate what the National Association of Scholars (NAS) had to say in a 2007 article titled 'The scandal of social work education'. The article accused social work educators of politicization that undercuts the intellectual foundations of the modern university, which the NAS described as the search for truth. They criticized what they saw as a trend in universities to doctrinaire ideological commitments, polemics in place of teaching, and political activism. Social work education, the NAS said, is an advanced case of politicization, and coerced intellectual conformity. It even went so far as to criticize the American Council on Social Work Education's protocol about affirming social justice ideals, stating that this has meant students have had their consciences coerced.

This criticism is disturbing as social workers are mandated, professionally and morally, to use their expertise, academic freedom, and professional networks to enact projects that scrutinize injustices and the flouting of human rights obligations. The question arises of moral responsibility and collective action when silence occurs. What is social workers' responsibility when people are effectively silenced through the political system, as has been the case with detained asylum seekers? The role of social work academics is crucial. As asserted by Noble et al., (2009: p. 415):

> To work in academic settings is a privilege that comes with both the opportunity and the responsibility to speak on behalf of those whose voices remain suppressed, or too weak to be heard.

Although tensions exist for social work educators, who have a degree of academic freedom, they are magnified for practitioners. Procedural control by organizations can result in limited scope for questioning of policies and practices decided at the corporate center (Hough and Briskman, 2003). Nonetheless, social work educators can assist students in finding a pathway through the limitations by helping them find a way to privilege social work principles rather than organizational tenets. Through instilling the courage to act, students can become moral agents (Ife, 2001). Role modeling by social work educators can inspire social work students to become advocates for asylum seekers. Students need to be cognizant of the risks of acting and not acting, and educators can take on a mentoring role.

Conclusion

Social work is a profession that is practiced within contradictory paradigms. The question remains as to how to position social workers as actors in the political realm of asylum seekers.

In a globalized world, social workers need to emerge from their own context to engage with the way in which dominant discourses are discordant with the value base of social work. Social workers can recognize their practice wisdom and reposition themselves as practice ethnographers. This entails drawing upon the knowledge derived through practice so that it does not merely remain within the annals of case notes and peer discussion, but can also contribute to social change. The experiential knowledge that resides within social work professionals themselves (Lyons et al., 2006) can be at the forefront of social work practice and advocacy.

Asymmetry of Body and Brain

Frank R Boutsen, College of Allied Health, Health Sciences Center, University of Oklahoma, Oklahoma City, OK, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Advances in computational analysis, imaging, and genetics along with increasingly sophisticated research paradigms have brought about an across-the-life-span, if not also an evolutionary, perspective in body and brain laterality research. In addition, a simple or naive structural localizationist approach to asymmetry in brain and body has given way to a developmental and physiological perspective. Evidence shows that asymmetries of body and brain are established early and share basic molecular pathways that are evolutionarily well conserved. That said, some genes show altered (asymmetric) expression levels in human brains and endow the brain unlike the viscera with lifelong adaptability.

Introduction

Although the basic body plan of vertebrates is essentially bilateral, all vertebrates lateralize unpaired organs of the chest and abdomen during embryogenesis. In humans this process leads to the characteristic positions of the heart apex, stomach, and spleen to the left of the midline but also to organ asymmetries as in the lung and heart with the primitive gut coiling itself in a counterclockwise direction (Kosaki et al., 1999; Cohen, 2001). Likewise, the brain while essentially symmetric also has structural asymmetries. Additionally, certain motor and cognitive functions appear to be hosted by one hemisphere more so than the other, promoting the idea of hemispheric specialization. Most basically limb motor control emanates from the contralateral hemisphere and thus is asymmetric from a central nervous system (CNS) axis point of view. This arrangement and other asymmetries in the nervous system are certainly not uniquely human (Corballis, 2014). However, as Geschwind and Miller (2001) and more recently Hervé et al. (2013) point out, the colateralization of hand preference and language dominance is quite unique and also an indicator that genetic underpinnings of body and brain asymmetry are different.

In humans, a link between cilia and L/R determination has been suspected since the discovery of Kartagener syndrome. Kartagener syndrome is an autosomal recessive genetic ciliopathy, also referred to as primary ciliary dyskinisia. In Kartagener patients, dynein arms (motor molecules) are absent from the respiratory cilia and sperm flagella. Leigh et al. (2009) reported that the prevalence of situs inversus totalis tends to be over 60% in the pediatric population, as opposed to 50% in the adult population. In addition, patients with Kartagener syndrome have a greater incidence of congenital cardiovascular defects, while a minority present with heterotaxy (heterotaxy according to Casey (1998) refers to any right/left abnormality including situs ambiguous and situs inversus). Bataille et al. (2011) described three patients with autosomal dominant cystic kidney disease, one presenting with dextro cardia and situs inversis totalis in the other two. Each harbored mutation in the PKD2 gene (vide infra).

More recently, Kosaki et al. (1999) described two Lefty gene mutations in patients with left-right anomalies that are homologues of Lefty-1 and Lefty-2 in the mouse model (vide infra). Gradient-wise expression of human Lefty may well be established by retinoic acid (RA) to which it binds. The patients' phenotype included cardiac abnormalities (e.g., left ventricle hypoplasia) and left pulmonary isomerism. Overall, these findings of heterotaxia point to a possible role of molecular signaling in heterotaxia.

Studies of conjoint twins have been most revealing as to the stage and possible embryonic mechanisms that are critical for normal body asymmetry. This is because conjoined twins are thought to originate from two adjacent embryonic streaks and tend to show situs abnormalities (Levin, 2001). This correlation, thus, invokes events surrounding the formation of the primitive streak as playing a critical role in the establishment of body symmetry.

Interestingly, according to Levin (2004, 2005) there is converging evidence that visceral and brain laterality are not correlated, even though they are statistically associated. He refers to studies by Kennedy et al. (1999) and McManus et al. (2004) showing that in right-handed individuals with situs inversus totalis left language lateralization occurs with the same frequency (95%) as it does in normal situs right-handed individuals while the incidence of left-handedness is also comparable to that in the rest of the population. Levin (2004) further notes that occurrence of unilateral anomalies on opposite sides of the head ("bookending" phenomena such as cleft lip, unilateral eye and ear defects) of otherwise healthy twins is not observed in the body.

Twin studies also point to difficulties of a purely genetic interpretation of laterality of brain function, including handedness (Annett, 2002; Klar, 2003). Klar (2003) suggests that lateralization of structure and function in the brain while certainly influenced by genetics is best interpreted within a developmental if not also a functional and even cultural perspective. On the other hand, familial occurrences of mirror movements (Peng and Charron, 2013), apraxia of speech, (Lai et al., 2001; Turner et al., 2013) and dyslexia (Galaburda et al., 2006; Graham and Fisher, 2013) indicate a molecular basis for lateralized limb motor control and left-lateralized speech and language if not also for hemispheric specialization in general.

MM are unwanted ipsilateral limb movements that co-occur with intended contralateral movements. While affecting mostly movements in the upper limbs, they can also interfere with or alter asynchronous (alternating) movements as in walking (Peng and Charron, 2013; Depienne et al., 2012). They result

from abnormal (re-)crossing of the corticospinal pathway at the level of the corpus callosum (CC), the medulla, or the spinal cord (Peng and Charron, 2013). A genetic basis for MM is evidenced in X-linked Kallmann syndrome. First described in 1944, this syndrome is characterized by hypogonadism and anosmia/hyposmia, presenting with MM (Peng and Charron, 2013). Dyslexia also has long been suspected to have a genetic underpinning as documentation of familial inheritance of this disorder goes back to the end of the nineteenth century (Galaburda et al., 2006). Not until recently, however, have MRI studies unveiled the incidence of periventricular nodular heterotopia and peri-Sylvian polymicrogyria in two groups of children with dyslexia suggesting a molecular disorder during embryogenesis (Galaburda et al., 2006). Perhaps the greatest advance in pinpointing the molecular basis for hemispheric specialization has been the discovery of the FOXP2 gene. Mutations of this gene were first identified in the KE family (Lai et al., 2001) and later in individuals with a small mutation having been discovered in an Australian family (Turner et al., 2013). In these families children present with childhood apraxia of speech, language, and literacy difficulties.

Intriguingly, Geschwind and Miller (2001) draw attention to the notion that understanding of the pathways involved in axis patterning and L-R establishment in particular may well advance understanding of degenerative brain disorders in the adult population, especially frontotemporal dementia (FTD). This is because FTD has been documented to involve asymmetric neurodegeneration that is familial, either presenting with primary progressive aphasia if left-sided or behavioral symptoms if right-sided (Geschwind and Miller, 2001).

Advances made in the above genetic lines of inquiry have been paralleled by improved imaging (e.g., Diffusion Tensor Imaging (DTI); Infrared Spectroscopy) and computational analysis techniques (e.g., Dynamic Component Modeling, Tractography) within the last decade (Hervé et al., 2013). As a result, an across-the-life-span perspective, starting *in utero*, is emerging showing an evolving relation between asymmetry in brain function and structure. Since much of the discovery regarding the asymmetry of body and brain pertains to human embryology that readers may not be familiar with early development is summarized based upon recent in-depth reviews provided by Sadler (2010) and Tan et al. (2013). The developmental time line (in days week^{-1}) is adopted from Sadler (2010).

Human Embryology: A Brief Review

The first 4 weeks of development, from fertilization until the end of gastrulation, is also known as blastogenesis. Blastogenesis establishes the first developmental field which comprises the entire embryo. The embryo proper initially is comprised of a cup-shaped single layer of primitive ectoderm, the epiblast, which is subsequently converted into the three definitive germ layers during gastrulation which include definitive ecto-, meso-, and endoderm. The primary field is then subdivided into progenitor fields, which give rise to primordia of all morphological structures. Organogenesis begins at the end of blastogenesis and is characterized by morphogenesis (formation of organs and other body parts) and histogenesis (differentiation of cells and tissues). It can be seen from this that the prospective adult body axes are fully laid out by the end of the blastogenesis while packaging (rotation of organs) continues during organogenesis. Brain development and laterality are established during differentiation; however, its development is also dependent on function.

Axis Formation and Positioning of Gut, Heart, and Central Nervous System

The axial blueprint for the body and brain is laid out very early during development. Upon sperm entry the fertilized zygote is corticalized. Mitotic division and subsequent cleavage produce by day 3 a spherical mass (early morula) that looks like a blackberry with isomorphic cells (blastomeres) that with compaction, flatten at the periphery (late morula, day 4) to become the first embryonic epithelium, the trophectoderm (later chorion and placenta).

The cells inside the compacted morula become the inner cell mass (ICM), and are totipotent. The dorsoventral axis is defined at the time of the blastocyst (**Figure 1**).

The future dorsal part of the embryo, contained in the ICM, is located at the contact of the blastocoele. In the next few days the blastocyst is implanted and the ICM evolves to become embryoblast (**Figure 1**). In the second week the embryoblast, through cell polarizaton, differentiates into a hypoblast layer (cuboid) and epiblast (columnar). As the amnion and primitive yolk develop dorsally and ventrally, respectively, extraembryonic mesoderm on the inner aspect of the trophoblast surrounds both. By day 12 the embryo reemerges on the endometrial surface. Isolated coelomic spaces appear in extraembryonic mesoderm and consequently fuse to form the extraembryonic coelom (chorion) that is limited by the chorionic plate (chorion is the embryonic component of placenta). This fluid-filled cavity surrounds the amnion and umbilical vesicle, except where they are attached to the chorionic plate by the connecting stalk. As the extraembryonic coelom forms, a second wave of hypoblast migration moves the primary umbilical vesicle away from the embryoblast to be pinched off for the most part. In its wake it is replaced by a secondary umbilical vesicle (the definitive yolk sac).

At the lateral aspects of the disc, extraembryonic coelom splits the extraembryonic mesoderm into extraembryonic somatic and splanchnic mesoderm that will cover the amnion (dorsal) and secondary umbilical vesicle (ventral), respectively. Somato mesoderm gives rise to somatopleure which is precursor to dermis and bone; splanchnic endoderm develops into splanchnopleure that will give rise to heart and blood vessels (vide infra). In the third week, during a process called gastrulation (**Figure 1**), ecto-, meso-, and endoderm are derived from the epiblast so that a trilaminar disc develops. The 14-day embryo still has the form of a flat bilaminar embryonic disc but the epiblastic cells in a localized area are now columnar and form a thickened circular area, the prechordal plate, which is an important organizer of the head region. Around day 16 the primitive streak forms as a groove in the midsagittal plane in the caudal half of the bilaminar disc (**Figure 1**). As the streak elongates, its cranial end thickens to

Figure 1 Early division, blastocyst, implantation, gastrulation, and neurulation stages of the developing embryo.

form a primitive knot or node that surrounds a depression termed the primitive pit (Figure 1). Near the primitive streak, epiblast cells delaminate as they undergo epithelial to mesenchym transformation (EMT) and ingress to displace hypoblast to form definitive endoderm. Definitive endoderm is a precursor to the gut tube and later fore-, mid-, and hindgut. In addition, epiblast cells migrate between endoderm and epiblast layers to form intraembryonic mesoderm except in two regions where the oropharyngeal and cloacal membrane form. Cells migrating from the cranial end of the node become the prechordal plate and notochord. Prechordal plate is a progenitor to cardiac mesoderm that forms in a horseshoe manner cranially to the oropharyngeal membrane. While over the course of this time the primitive streak has been shrinking to ultimately disappear, cephalocaudally the notochord makes its appearance as a tunnel under the dorsal surface of the trilaminar embryo. The notochord is located in the rostral half of the presomite embryo and underlies the midline of the neural plate (head plate) that at day 19 is clearly visible. On day 20 neural folds form cranially and a neural groove is visible centrally that is flanked by the first pair of somites in the occipital region of the embryo (Figure 1). Somitization proceeds cephalocaudally and segments paraxial mesoderm along its anterior-posterior (AP) axis. The first somitomeres develop in the head region in association with segmentation of the neural plate into neuritomeres. Cephalad expansion of the developing neural tube along with the endoderm below it results in folding at the cranial end of the embryo's AP axis so that both initially extend over the future pericardial cavity. Ventrally the endoderm is continuous with the yolk sac that is suspended from it in a teardrop shape. Folding of endoderm (superior to the yolk sac) forms the gut tube, which is a progenitor of the gut. Meanwhile, the neural fold expands anteriorly and curves underneath the anterior aspect of arched endoderm leaving space for the developing heart tube and liver that are situated anterior to the superior convergence (neck) of the yolk sac. Thus, at this point aspects of the adult AP axis (in supine position) are established as the brain primordia are in front of those the heart which are in turn in front of the midgut. In addition, aspects of the adult dorsoventral axis are also established where the neuraxis is dorsal to the heart (tube) and gut (tube). As the neural folds continue to elevate they approximate at the

midline dorsally and finally fuse around day 22 in the center of the AP axis leaving unfused areas (neuropores) cranially and caudally. At this point segmentation of the paraxial mesoderm is well underway as seven somites are visible alongside the developing neural tube. In addition, at day 23 the heart tube proliferates causing a bend halfway along its craniocaudal axis and also rightward twisting to form the atrium cranially and the ventricle caudally. Final closure of the cranial neuropore occurs around day 25 at the 18–20 somite stage. At this point neural crest cells (Figure 2) differentiate from neuroectoderm above the neural tube and induce the first and second pharyngeal arches ventrally in head mesenchyme. They are positioned anteriorly to the heart tube that completes rightward cardiac looping around day 28. Around day 28 the caudal neuropore closes as well at which time 25 somites have formed. At this point blastogenesis is complete and the embryo is formed along major body axes. The neural tube is formed between right and left chains of somites (Figure 2). It has been derived from neuroectoderm. Pharyngeal (branchial) arches are visible. The embryo is now slightly curved because of the head and tail folds. The heart produces a large ventral prominence and pumps blood. The forebrain produces a prominent elevation of the head, and folding of the embryo has given the embryo its characteristic C-shaped curvature. A long, curved tail is present. Upper limb buds become recognizable by day 26 or 27 as small swellings on the ventrolateral body walls.

Figure 2 Neural crest cell develop upon closure of the neural tube. The neural tube expresses a roof plate, floor plate, and the sulcus limitans along its length.

Central Nervous System Development: Anterior-Posterior Partitioning

In the 5th week the neural tube expands to form 3 vesicles that pattern its AP axis into fore-, mid-, and hindbrain and future spinal cord. The dorsoventral axis of the lumen of the neural tube is expressed by the appearance of the sulcus limitans (Figure 2). The human cerebral hemispheres originate at about 6 weeks in the embryo, growing from the midline at the rostral end of the neural plate in the morphologically symmetric prosencephalic vesicle. At 7 weeks the prosencephalon divides into diencephalon and telencephalon while the hindbrain divides in metencephalon and myelencephalon. At 8 weeks the two hemispheres become clearly delineated by an interhemispheric fissure, which divides the two cerebral hemispheres.

Cortical Specification

The cortex is formed at the rostral-most portion of the neural tube and is quickly subdivided in the left and right telencephalic vesicles. Cortical neurons are generated from dividing progenitor cells in the ventricular zone (VZ) layer (Figure 3; Buckner and Krienen, 2013; Monuki and Walsh, 2001).

Guided by neuroglia (Figure 3) most postmitotic neurons migrate radially and enter the cortex which will develop from the inside out as is shown in Figure 4: layer I will develop before layer II and so on (Cooper, 2008).

Limited expansion medially between the telencephalic vesicle creates the dorsal midline roof plate while medially in the ventral region of the vesicles continued expansion produces the ganglionic eminence (the future basal ganglia; see Figure 5) that will be an important source of GABA neurons.

Meanwhile, the cortex becomes exposed to several potential sources of secreted signaling molecules or organizers (Buckner and Krienen, 2013; Monuki and Walsh, 2001). They include in order of their development, the anterior neural ridge (ANR), the roof plate, the cortical hem, and other sources of signaling molecules, such as the surface ectoderm (the future skin) and mesenchymal elements between the skin and brain, including the future meningeal cells that surround the adult brain (vide infra). After its initial induction by extrinsic signals, the telencephalon becomes specified into dorsal (pallial) and ventral (subpallial) regions. Following dorsal telencephalic specification, the dorsal telencephalon must be further subdivided into dorsal midline epithelial fates (choroid plexus epithelium and cortical hem) and the cortical VZ. Once the cortical VZ fate is selected, regional specification of the cortical VZ occurs (Buckner and Krienen, 2013; Monuki and Walsh, 2001).

The CC develops relatively late, i.e., around the 12th week (Sadler, 2010). Choe et al. (2012) note that CC development awaits midline glial specializations and guidance cues from

Figure 3 Histogenesis in the cerebral cortex proceeds through three stages. In the first stage of histogenesis, the wall of the cerebral cortex is made up of the progenitor cells, which occupy the VZ. In the next stage of development, the first neurons exit the cell cycle (red) and accumulate in the preplate, adjacent to the pial surface. The neurons of the preplate can be divided into the more superficial Cajal-Retzius cells and the subplate cells. In the next stage of cortical histogenesis, newly generated neurons (red) migrate along radial glial fibers to form a layer between the Cajal-Retzius cells and the subplate. This layer is called the cortical plate, and the majority of the neurons in the cerebral cortex accumulate in this layer. Modified from Noctor, S.C., Martinez-Cerdeno, V., Ivic, L., Kriegstein, A.R., 2004. Cortical neurons arise in symmetric and asymmetric division zones and migrate through specific phases. Nature Neuroscience 7, 136–144; Noctor, S.C., Martlnez-Cerdefio, V., Kriegstein, A.R., 2008. Distinct behaviors of neural stem and progenitor cells underlie cortical neurogenesis. Journal of Comparative Neurology 508, 28–44.

the septum underlying the callosum that do not normally develop until just before the callosal pathfinding axons project across the midline. These cues regulate the

Figure 4 In normal cortical development the early generated neurons bypass the previously generated neurons to produce the inside-out developmental ordering to the lamination.

connectivity of the two hemispheres, as well as the formation of other ascending and descending tracts. They further mention that later-born neurons (layers 2–4) may yet be another source of delay for CC formation as they, along with layer V neurons, are primary sources of callosal axons. Interestingly, Buckner and Krienen (2013) cite evidence from the Allen Brain Institute that genes with species-specific expression patterns in mouse and humans are expressed asymmetrically in cortex. That is, according to these data, mouse brain showed a preponderance of markers in layer V (projection neurons), whereas half these markers showed either no or diminished expression in humans. On the other hand, in humans more of these genes were expressed in layer III (cortico-cortical projection neurons). According to Buckner and Krienen (2013), this finding supports the notion that these layer-III pyramidal neurons with long-range intracortical projections could well be important for the patterning of association cortex (see also role of FOXP2 below). Finally, as it pertains to the development of cortical folds, Geschwind and Miller (2001)

Figure 5 The neurons of the cerebral cortex derive from both intrinsic and extrinsic sources. Most of the neurons in the cortex are derived from the VZ cells immediately below their adult location. (a–c) This figure shows the paths taken by the neurons from the ganglionic eminence in red at low (a,b) and high magnification (c) and the neurons generated within the cortex in green. Modified from Kriegstein, A.R., Noctor, S.C., July 2004. Patterns of neuronal migration in the embryonic cortex. Trends in Neurosciences 27 (7), 392–399.

report that at 26 weeks of gestation, the superior temporal sulcus (STS) is easily distinguished, followed by the angular and supramarginal gyri of the parietal lobe at 28 weeks of gestation. The transverse temporal gyrus appears at 31 week (Geschwind and Miller, 2001).

Asymmetry

Body

The tissue movements initiated during gastrulation eventually establish the distinct left-right orientation of the developing viscera. According to Constam and Robertson (2000) L-R asymmetry first becomes visible after the formation of 8–10 somite pairs when the primitive heart tube loops to the right side. Shortly thereafter the entire embryo turns rightward 180° while concurrently ventral folding of the gut endoderm and embryonic body wall fold results in ventral closure. Constam and Robertson (2000) note that the coordinated timing of axial rotation and ventral closure suggests that they may be regulated by the same molecular signals, i.e., the asymmetric expression of several genes, including the TGFβ family members Lefty-1, Lefty-2, and Nodal (see below) that precedes both processes. More recently, Yamaguchi (2001) concluded that Wnt and Bmp (Wingless first identified in Drosophilia and bone morphogen proteins) inhibitory signals from the midline anterior neural tube and notochord ensure that the heart-forming region remains lateral by inhibiting cardiogenesis in the adjacent paraxial mesoderm (vide infra).

Brain Asymmetries

The earliest sign of anatomical asymmetry so far identified in human fetuses, shows the choroid plexus to be larger on the left than on the right in approximately two-thirds of fetuses in the 11th to 13th week of gestation and this asymmetry may well underlie asymmetry of the planum temporale (Corballis, 2013).

Geschwind and Miller (2001) report evidence that planum temporale and peri-Sylvian language asymmetry areas are first visible around 30 weeks gestation in most human fetuses. These peri-Sylvian structures are visible earlier on the right than on the left by about 1 week.

Likewise, studies by Gilles (1983) and Jammes and Gilles (1983) report that the transverse temporal gyrus, which

appears at 31 week, is observed 1 ± 2 weeks earlier on the right in most fetuses.

Hervé et al. (2013) in a review of imaging evidence and hemispheric specialization report that multiple imaging studies *in utero* or in preterm newborns have reported a larger planum temporale and deeper right STS. Additionally, these studies reveal that sulcal pits (deepest and also earliest parts of cortical sulcal fundi) are more frequent and less variable in the left than the right STS extremities (Hervé et al., 2013). Consistent with these findings are data from Li et al. (2013), who investigated cortical hemispheric asymmetry from birth to 2 years of age. They found that the cortical asymmetries around the peri-Sylvian region and STS evolve modestly from birth to 2 years of age. At birth, males showed larger asymmetries than females and this difference persisted from birth to 2 years of age. Specific asymmetries shown included the left supramarginal gyrus (SMG) being significantly posterior to the right SMG (10.2 mm for males and 6.9 mm for females at birth growing to 12.0 and 8.4 mm by 2 years of age). In addition, they found that the right STS and parieto-occipital sulcus are significantly larger and deeper than their counterparts in the left hemisphere while the left planum temporale is significantly larger and deeper than that in the right hemisphere.

As for white matter, Dubois et al. (2009) conducted a DTI study in 1- to 4-month-old newborns. For each infant the arcuate fasciculus and corticospinal tract were reconstructed using tractography. Whole brain voxel-based and region-specific fractional anisotropy (FA) analyses revealed greater FA in the left compared to the right arcuate fasciculus as well as in the lower aspect of the corticospinal tract, i.e., the segment between the insula and the cerebral peduncle. These results are consistent with DTI findings by Buchel et al. (2004) in adults who found left greater than right FA white matter asymmetries in the arcuate fasciculus along with asymmetries in tracts contralateral to the dominant hand (i.e., higher on the left in right-handers) innervating the precentral gyrus.

In terms of a functional or hemispheric dominance perspective, Corballis (2013) cites evidence from ultrasound recordings that fetuses as early as 11 week of gestation show more movement of the right than of the left arm, and from 15 weeks some 90% of fetuses suck the right rather than the left thumb, an asymmetry that according to Hepper et al. (2005) correlates with handedness at 10–12 years of age. Lin et al. (2013) employed frequency-domain near-infrared spectroscopy to measure hemodynamic and metabolic parameters in newborns and found that they were greater in the temporal and parietal regions than in the frontal region and that these differences increased with age. In addition, most parameters were significantly greater in the right hemisphere than in the left. Compared to age-matched females, males showed greater left than right asymmetry (Lin et al., 2013). On the other hand, Hervé et al. (2011) only found modest T2 signal asymmetry in CST associated with handedness on DTI with 7-T (Tesla is a unit of measurement quantifying the strength of a magnetic field, 7 being ultra-high-field) and were unable to corroborate their earlier finding (Hervé et al., 2009) of greater T1 asymmetry in CST.

Overall, as Li et al. (2013) point out early brain development data indicate sequential development of asymmetry giving primacy to right over left development which is in agreement with the "Right-hemisphere conservatism" theory proposed by Geschwind and Galaburda (1985). Along this line they speculate that early (*mine*) right hemisphere development is protective, since it shields this hemisphere from external influences while the delay in maturation of the left hemisphere may allow for a higher plasticity with functional stimulation, such as language exposure and motor activity (perhaps at the cost of exposure). The delayed expression in the left hemisphere may also be responsible for the left lateralization of sensorimotor control or praxis (Lin et al., 2013). As this takes place there may be subcortical white matter "spurts" that may be greater in the left than in the right giving rise to greater connectivity (vide infra).

Molecular Basis: Signaling Pathways and Gradients

The molecular basis for transformation and patterning of existing into new tissue involves distant and gradient signaling to accomplish spatiotemporal timing of processes often lasting as short as a few hours (Field et al., 2011; Yang, 2012). While there appears to be a redundancy of pathways and genes that can participate in this space-time clock, much of its integration if not coordination seems to be at the level of SMAD receptors that are in much more limited supply (SMAD is a portmanteau for MAD (mothers against decapentaplegic, in Drosophilia (Heldin et al., 1997) and SMA for small body size in *Caenorhabditis elegans* (Savage et al., 1996)) introducing an element of competition as it were among genes/pathways (Inui et al., 2012; De Robertis and Kuroda, 2004). Most basically, molecular signaling affects transformation in existing tissue by undoing and altering the existing cell arrangements (delamination, EMT) in a directional (polarization by Planar Cell Polarity (PCP)) and hierarchical and patterned manner. At the cellular level this involves developmental processes including establishment of polarity and changes in cytoskeleton (microtubules) and (symmetric and asymmetric) division affecting expansion while intercellular processes such as gene transcription or repression instruct processes including cell adhesion (as in compacting or loosening) and guidance (chemo-attraction/repellents, affinity to glial guidance). At the same time molecular signaling informs the timing of cell fates ranging from toti/pluripotent (as in morula or later in VZ) to committed. Regional (patterned) development depends not only on distant intercellular signaling for the dispersion of genes but also on the establishment of temporary organizers. Examples of the latter include the primitive streak, the primitive node (also termed Hensen's node and Spemann-Mangold organizer, see Niehrs (2004) for review) in mesoderm, the head organizer, the notochord, the neural plate, the ANR, cortical hem (and antihem), and glial cells.

Intercellular signaling results in the activation of intracellular proteins and factors through a well-defined cascade that eventually initiates or represses the transcription of specific genes. Based on their shared molecular structures four

Figure 6 Hox genes are important in the anterior-posterior patterning of the embryo.

signaling families are distinguished (Tan et al., 2013). They include the Hedgehog (Sonic Hedgehog or Shh), Wnt (canonical and noncanical), Fibroblast Growth Factor (FGF), and transforming growth factor-β families (TGFβ). Important targets of this signaling include Homeobox or HOX genes (**Figure 6**) and BMPs. As can be seen in **Figure 6** Hox genes are important in antero-posterior patterning of the embryo.

Processes Laying the Ground Work for Asymmetry

Planar cell polarization is evidenced by uniform asymmetrical localization of key polarity protein and uniform asymmetrical cellular behaviors such as the localization and orientation of cell extensions like cilia. Examples of PCP-regulated processes are uniform orientations of drosophila hair, mouse fur, inner ear sensory hair cells, elongating antero-posterior body axis and closing neural tubes (Yang, 2012). In a context-dependent manner, the directional information provided by PCP is essential for cells to decide in which direction to divide, to move, or to interact with each other (Yang, 2012).

Like the PCP pathway, Nodal, a member of the TGFβ family, partakes in very early signaling in mouse, Nodal is expressed throughout the epiblast and induces formation and anterior movement of the anterior visceral endoderm (AVE) 1 day before gastrulation (Yamamoto et al., 2004; Tan et al., 2013). In doing so, it plays a crucial role in establishing the proximal distal axis (which is a primordial AP axis). Yamamoto et al. (2004) cite evidence that the AVE secretes signaling molecules, including the Nodal antagonists Lefty-1 and Cerl both of which will inhibit Nodal signaling in the underlying epiblast and restrict Nodal activity to the posterior side of the embryo. Such asymmetry in Nodal signaling specifies that the anterior epiblast will form the prospective brain and generates the primitive streak on the posterior side (Yamamoto et al., 2004). It can be seen from this that reductions of Nodal pathway activity albeit indirectly can result in phenotypes resembling human holoprosencephaly.

The Wnt pathway, originally described as the wingless pathway in Drosophila, is involved in axis formation and regionalization of the vertebrate body and nervous system (**Figure 7**) (Geschwind and Miller, 2001). As a morphogen it can form a concentration gradient across a field of hundreds of cells which leads to the generation of different cell types in a distinct spatial order (Yamaguchi, 2001; Yang, 2012). While

Figure 7 Gradient expression of Wnt, retinoic acid (RA) and FGF is involved in anterior posterior patterning of the embryo. It regulates expression of otx2 which reflects the basic division between the rostral brain and the hindbrain and spinal cord. Otx2 expression is depicted at various stages of embryonic development in the chick brain. Otx2 is expressed in the anterior neural plate (a) and remains expressed in most of the brain throughout development (b–e). The arrowhead points to the midbrain-hindbrain boundary. (e) The relationship between the three transformer signals and the expression of otx2 and gbx2. Modified from Millet, S., Bloch-gallego, E., Simeone, A., Alvarado-Mallart, R.M., 1996. The caudal limit of Otx2 gene expression as a marker of the midbrain/hindbrain boundary: a study using in situ hybridisation and chick/quail homotopic grafts. Development 122 (12), 3785–3797.

Yamaguchi has detailed the importance of Wnt role in vertebrate axis formation and heart development in particular, Yang (2012) recently has described how Wnts are involved in regulating PCP and in doing so by way of their gradient expression provide quantitative information to generate a distinct pattern as in proximal distal limb bud patterning. Interestingly, Wnt along with Shh upstream from it also involved in cleft lip pathogenesis (Kurusaka et al., 2014)

FGF signaling is essential to delimit the expression domain of BMPs as early as the blastula stage (Arnold and Robertson, 2009). Initially BMPs are expressed throughout the bilaminar disc. According to Thisse and Thisse (2005), FGF signaling represses BMP expression dorsally, thus delimiting BMP expression to the ventral embryo. FGF activity thus is an essential factor in the early establishment of dorsoventral patterning (Fürthauer et al., 2004). As reviewed above "dorsalization" in the embryo (see **Figure 8**) involves the development of the primitive streak and its replacement by growing notochord. Movement patterns of anterior streak cells can be explained by an FGF8-mediated chemorepulsion of cells away from the streak followed by chemoattraction toward an FGF4 signal produced by the forming notochord (Yang et al., 2002). Toyoda et al. (2010) recently has shown that in mouse FGF8 establishes a gradient along the AP axis of the neocortical primordium. They cite evidence that the anterior source of FGF8 and FGF17 is an integral patterning center for the entire neocortex (Toyoda et al., 2010).

The HOX gene families are members of the Homeobox superfamily of genes (Sadler, 2010; Tan et al., 2013). The HOX genes are partly responsible for determining the AP axis in the developing embryo (see **Figure 6**) and regulate the formation of musculoskeletal structures in each body segment (Tan et al., 2013). Timed transcription of different Hox genes lined up in AP axis involves a retinoic acid (RA) gradient (**Figure 7**) that is low anteriorly and high posteriorly (Tan et al., 2013). Together they make up an important part of the segmentation clock. Pitx2 is a Homeobox gene that is important in L-R axis asymmetry and organogenesis (Field et al., 2011).

Left-Right Asymmetry Body (Organs)

Understanding the initiation of left-right axis formation has been quite a challenge. Unlike the anterior-posterior and dorsoventral axes with which it is coordinated there are no exogenous cues (e.g., gravity or point of sperm entry) that serve as reference points for its determination (Levin, 2001; Arnold and Robertson, 2009). The "two cilia hypothesis" which has gained traction in recent years offers real promise toward solving this conundrum (Nakaya et al., 2005; Tan et al., 2013). During gastrulation, cilia emanating from the ventral surface of the primitive node play a crucial role in the "breaking" of bilateral symmetry (McGrath and Brueckner, 2003). Recently, Yang (2012) has pointed out that PCP is involved in the polarization of the node cells and in the uniform curved shape of the cilia. This is because the net

Figure 8 Dorsalization and ventralization of the embryo comprise balanced development of nervous system (red) and heart-gut formation (blue). (a) Normal development of a Xenopus embryo. (b) uV light treatment of the early embryo inhibits the development of dorsal structures by disrupting the cytoskeleton rearrangements that pattern the dorsal inducing molecules prior to gastrulation (ventralized). (c) Lithium treatment of the early embryo has the opposite effect; the embryo develops more than normal dorsal tissue (i.e., hyperdorsalized). (d) If messenger RNA is extracted from the hyperdorsalized embryos and injected into a uV-treated embryo, the messages encoded in the mRNA can "rescue" the uV-treated embryo and it develops relatively normally. (e) Similarly, cDNA from the organizer region of a normal embryo can rescue a uV-treated embryo.

leftward flow of extraembryonic fluid at the node is thought to be generated by motile curved cilia that are positioned in the posterior aspect of the node cells. In addition, nonmotile mechanosensory cilia, sense Nodal flow on the left side of the node and convert it into an asymmetric Ca2+-dependent signal transduction event that upregulates Nodal on the lateral plate mesoderm (LPM) (Yang, 2012; Tan et al., 2013). The two cilia hypothesis is consistent with studies by Pennekamp et al. (2002) and McGrath et al. (2003), who found that mutations in the polycystic kidney disease 2 (Pkd2) gene that partakes in the generation of asymmetric Ca2+ flux cause abnormal LR development.

It now has been well-documented across vertebrates that LPM Nodal partakes in a cascade of events (Hamada et al., 2001; Yamaguchi, 2001). That is, upstream, Nodal activity is upregulated by Notch pathway activity (Shh) and downstream by Nodal itself in a positive feedback loop (Field et al., 2011). Autoactivation of Nodal results in rapid spread throughout the left LPM along with the induction of Lefty-1 and Pitx2 expression. Nodal is then quickly downregulated by Lefty-2 via a negative feedback loop. Lefty-1 most likely acts as a molecular barrier preventing left-sided Nodal signals to cross to the right side. More recently, Nakaya et al. (2005) reported evidence that Wnt, expressed in the primitive streak and dorsal posterior node, acts as a long-range signaling molecule, directly regulating target gene expression throughout the node and presomitic mesoderm.

Nodal expression in the left LPM occurs around the 2–4 somite stage and is turned off by the 8 somite stage (Nakaya et al., 2005). Pitx2 continues to be expressed well past this point and partakes in the lateralized morphogenesis of the heart (Field et al., 2011). Even so, the details of the coupling of somitogenesis and L-R axis are still not well understood (Nakaya et al., 2005). One possible mechanism proposed by Yost (1992) involves (polarized L-R) fibrils that are attached to the ectoderm. These fibrils supposedly change their orientation from parallel to perpendicular to the AP axis during neurulation at which time, coincident with movement of the cardiac and gut primordia across the extracellular matrix, the ectoderm is stretched by elongation of the embryo in the anterior-posterior axis.

Brain: Molecular Pathways Setting the Stage for Organizers and Cortical Patterning

Monuki and Walsh, 2001 summarized the hierarchical arrangement of molecular pathways and establishment of organizers in a recent review of the molecular pathways involved in telencephalic development as follows. Initially, Fgf8-Foxg1 is involved in the induction of the ANR whereas HPE genes, including Shh promote the dorsal midline roof plate. From here on, in their account genetic/molecular pathways diverge from those described above in blastogenesis (although, see also Geschwind and Miller (2001 and Choe et al., 2012) below) for the continued role of Wnt. That is, dorsalization of telencephalic tissue is specified (Neurogenins and Gli3) and a cortical VZ fate is selected from other dorsal fates by Lhx2. The cortical VZ then becomes regionally specified and signaling molecules, including those from the dorsal midline region (roof plate and cortical hem), then act on the cortical VZ to regulate its expansion. Relative sizes of cortical VZ fields and ultimately cortical areas are being determined by gradients of intrinsic transcriptional regulators Emx2 and Pax6 (Muzio and Mallamaci, 2003 see **Figure 9**).

Interestingly, Buckner and Krienen (2013) cite evidence by Fukuchi-Shimogori and Grove (2001), who demonstrated that varying FGF8, in its normally occurring anterior location of the telencephalon, could expand and contract the somatosensory map of the adult mouse cerebral cortex (see **Figure 10**).

Additionally, they showed that by unnaturally expressing FGF8 in a second posterior location a duplicate somatosensory map of mouse barrel cortex was formed (Buckner and Krienen, 2013).

As stated above CC development with axons actually crossing the midline is relatively late. Choe et al., 2012 found

Figure 9 Two transcription factors critical for the specification of regional identities in the cortex are Pax6 and Emx2. Emx2 is expressed primarily in the posterior cerebral cortex and then gradually diminishes in expression toward the rostral cortical pole; Pax6 has the complementary pattern of expression. Loss of either the Pax6 gene or the Emx2 gene affects the cerebral cortical pattern of development. In the wild-type (wt) animal, the motor cortex (m) is primarily located in the rostral cortex, and the other sensory areas for somatosensation (S), auditory sensation (A), and visual perception (v) are located in the middle and posterior cortex, respectively. In the Emx2-deficient mice, the pattern is shifted caudally, and a greater area is occupied by the motor cortex; by contrast, in the Pax6-mice the visual cortex is expanded and the motor cortex is severely reduced. Modified from Muzio, L., Mallamaci, A., 2003. Emx1, emx2 and pax6 in specification, regionalization and arealization of the cerebral cortex. Cerebral Cortex 13 (6), 641–647.

that this late development is effected by BMP7 that serves as a barrier to early projection of axons across the midline. They cite evidence that early CC development involves cingulate (pioneer) neurons adjacent to the Cajal-Retzius cells and meningeal tissues. Wnt3 expression by these cells and as well as indirect Wnt control by the meninges allows them to overcome the negative effects of BMP7 (Choe et al., 2012).

Central Nervous System Asymmetry

Several genes including ROBO (roundabout) and Ephrin signaling pathways (see **Figure 11**) have been shown to be involved in axon crossings in the CC as well as in the medulla and spinal cord. (Kullander et al., 2001; Paixão et al., 2013). That said, consistent with the observation that congenital MM (abnormal midline crossing(s) of CST) primarily affect the upper limbs, mutations in them do not always show interference with alternating movements in gait (Depienne et al., 2012; Paixão et al., 2013; Peng and Charron, 2013). Peng and Charron (2013) report that the first mutation specifically linked to congenital MM without additional neurological defects in humans (i.e., "essential" MM) was in deleted in colon cancer (DCC). More recently a mutation in the RAD51 gene has been shown to produce MM as well (Depienne et al., 2012). DCC is a receptor involved in axon guidance and midline crossing in particular by binding to Netrin to promote a chemoattractive response (Depienne et al., 2012) Rad51 is a gene involved in DNA repair but may also specifically be involved in axon crossing at the pyramids in mouse (Depienne et al., 2012). There is also evidence that Shh made by floor plate cells collaborates with netrin-1 in midline attraction (Ly et al., 2008). Peng and Charron 2013 note that in the DCC mutant family males are more affected than females and that this could perhaps indicative of sex differences in CST development.

Seminal studies by Sun et al. (2005), and Sun and Walsh, (2006) reveal significant asymmetries of gene expression in embryos as early as 12 weeks gestational age. In particular, the transcription factor LIM-only protein 4 (Lmo4) gene is consistently more highly expressed in the right peri-Sylvian cortex than in the left. Lmo4 relates to the regulation of normal sensorimotor control (Huang et al., 2009). Specifically, studies by Cederquist et al. (2013) and Huang et al. (2009) reveal that Lmo4 establishes molecular anatomical diversity of motor control projection neurons within the motor cortex and this diversity of neuronal connectivity centrally includes the development of dual projection neurons that integrate sensory and motor information within the same hemisphere and across hemispheres.

Monuki and Walsh (2001) recently concluded that FOXP2 may be a candidate gene in peri-Sylvian polymicrogyria, which results in difficulties with swallowing, articulation, and language acquisition as well as frequent and severe seizures. They further state that because of its regional nature this disorder may well involve a gene mutation that regulates later events in cortical patterning and thus causes subtle rather than gross malformations of the cortex along with mild cognitive and behavioral defects. In addition to cortical patterning, several lines of studies suggest that FOXP2 in mice and humans acts to regulate dopamine and corticostriatal function related to motor learning (Enard et al., 2009; Murugan et al., in this issue). Galaburda et al. (2006) cite two reports, one describing 8 dyslexic cases with the neuronal migration anomaly and periventricular nodular heterotopia (Chang et al., 2005), and 13 children with peri-Sylvian polymicrogyria and developmental language deficits (de Vasconcelos Hage et al., 2006). The most consistent findings in the original cases are nests of neurons, termed ectopias, in cortical layer 1 and occasional focal microgyria affecting language areas (Galaburda et al., 2006). Additional defects in the thalamus and cerebellum, together with the cortical changes, are proposed to explain the dyslexic phonological deficits, as well as the auditory discrimination and motor deficits that occur in some cases (Galaburda et al., 2006; Giraud and Ramus, 2013). DYX1C1, KIAA0319, DCDC2, and ROBO1 are reported to be dyslexia candidate susceptibility genes (Galaburda et al., 2006; Giraud and Ramus, 2013). The proteins encoded by these genes may be functionally linked in pathways involved in neuronal migration and axon growth. (Galaburda et al., 2006; Graham and Fisher, 2013). In this regard, it is of note that subcortical white matter abnormalities have been demonstrated in recent studies using DTI. Interestingly, Rimrodt et al. (2010) used

Figure 10 Fgf8 patterns the cerebral cortex. (a) Fgf8 is expressed at the anterior pole of the developing telencephalon, while BmPs and wnt genes are expressed in the posterior pole. Grove and her colleagues have misexpressed Fgf8 in different positions within the developing cortex. (b) In the normal mouse, the barrel fields of the somatosensory map (yellow) are located near the middle of the cerebral cortex, while Fgf8 (red) is expressed anteriorly and BmP (blue) is expressed posteriorly. (c) Increasing the amount of Fgf8 (red) in the anterior pole causes a caudal shift in the cortical regions, including the somatosensory map. (d) Placing a bead of Fgf8 in the caudal cortex causes the formation of a duplicated, mirror image of the somatosensory map. (e) micrograph of duplicated somatosensory maps after the addition of an ectopic Fgf8 bead. Wp1 is the original map and Wp2 is the new map. Modified from Grove, E.A., Fukuchi-Shimogori, T., 2003. Generating the cerebral cortical area map. Annual Review of Neuroscience 26, 355–380.

DTI and tractography and concluded that atypical white matter connectivity (and orientation) especially in the left inferior frontal gyrus in dyslexic participants may well be the result of cortical patterning abnormalities.

As for asymmetric degenerative disease, Geschwind and Miller (2001) entertain the idea that molecular pathways involved in L-R asymmetry in embryonic development may be at play in asymmetric degeneration. Specifically, they implicate the Wnt pathway since it regulates Tau which has been shown to be deficient in FTD.

Substrates Underlying Cerebral Dominance

Over the years cerebral dominance has been defined as the hemisphere where language and hand preference are uniquely colocalized in the majority of people. This uniquely human cerebral arrangement has led to biased views of cerebral asymmetry where the left hemisphere is more special than the right and that uniquely human genetics make it so (see Corballis (2014) for a recent review on facts and fantasies surrounding left brain-right brain). That is, left-right structural asymmetries are often seen as caused by genetics that are "special." While some substitutions on FOXP2 gene indeed appear quite recent (Graham and Fisher, 2013) and the data by Sun et al. (2005), and Sun and Walsh (2006) point to a set of uniquely human genes that have recently evolved, a recent study by Jahanshad et al. (2010) point out that environmental factors codetermine cerebral asymmetry along with genetics. These investigators used DTI and a twin/sibling design to map the 3D pattern of asymmetries and to search for regions where these

Figure 11 Comparison of conserved mechanisms of midline crossing in vertebrate and fly. Top: filleted vertebrate preparation, obtained by dissecting the embryonic spinal cord of the chick and the embryonic Drosophila ventral nerve cord. Homologous guidance molecules (particularly Netrins and Slits) are expressed at the ventral midline. Bottom right. In flies, Comm in precrossing axons binds to newly made Robo coming from the Golgi apparatus and sorts it to the late endosome for degradation. Bottom left. In vertebrates, Robo3 antagonizes Robo1 to allow crossing in mice. In precrossing commissural axons, Robo3 levels are high, and Robo1 levels low. Robo3A inhibits Robo1-mediated repulsion in these axons so that they are instead attracted to the floorplate by Netrin-1 and Shh. After crossing, Robo3A is replaced by Robo3B, and Robo1 activity is high. Axons are now repelled by signaling of Slit through Robo1. In addition, attraction to Netrin is downregulated, owing to a slit-dependent interaction between Robo1 and DCC. From Dickson, B.J., Gilestro, G.F., 2006. Regulation of commissural axon pathfinding by slit and its Robo receptors. Annual Review of Cell and Developmental Biology 22, 651–675.

asymmetries are highly heritable and thus may be accounted for by genetics. Using this statistical method they report significant asymmetries in FA with frontal R > L and temporal L > R regions. Interestingly, regional analysis of FA asymmetry shows that genetic factors account for 33% of the variance in the inferior fronto-occipital fasciculus, 37% of the variance in the anterior thalamic radiation, and 20% of the variance in the forceps major and the uncinate fasciculus. In addition, shared environmental factors account for about 15% of the variance in the corticospinal tract and about 10% of the variance in the forceps minor. Jahanshad et al., 2010 further report higher similarities in the intraclass correlation maps among monozygotic compared to dizygotic twins, thus providing additional support for the notion that fiber asymmetries are genetically influenced. The overall finding of genetic and (random) environmental factors playing a role in cerebral asymmetry is in line with the proposal that there might be a "right-shift" gene or perhaps more likely a set of "right-shift" genes along with random environmental factors influencing the degree of cerebral dominance and lateralized behavior such as handedness (Annett, 2002. Suzuki and Ando, 2014).

As to the role of the CC in functional asymmetry, Josse et al. (2008) combined DTI assessment of the CC and functional MRI and found revealed that CC size was positively correlated with left lateralization for single word naming and semantic decision tasks. Replicating an earlier measurement by Witelson (1989) it was also shown that in the Hofer II subdivision of the CC, right-handers have a smaller midsaggital surface area than non-right-handers. Faced with this apparent disparity, Josse et al., 2008 concluded that language lateralization is stronger when CC size is larger and that the effects of CC on handedness

and language lateralization are independent. Interestingly, analysis of CC size and language lateralization data in terms of increased/decreased left-right hemisphere activation patterns shows that the effect of CC size on posterior temporal activation is partly driven by right hemisphere inhibition, whereas the effect of CC size on inferior frontal activation is explained by increased information transfer to the left hemisphere from right hemisphere homolog or heterolog regions (Josse et al., 2008).

Aside from the CC, the corticospinal tract has been considered a possible (localized) substrate for hand dominance. As stated above a recent investigation by Hervé et al. (2011) using a Tesla 7 MRI scanner found a leftward asymmetry in the internal capsule in T2 measurements in non-right-handed persons but were unable to confirm T1 asymmetry shown in an earlier DTI study in this group (Hervé et al., 2009). Hervé et al. (2011) caution that while this finding could suggest a greater myelination of the internal capsule in their "motor dominant" hemisphere, the effect was not specific to motor fibres of the CST and was also observed in a small group. Perhaps more revealing are two recent DTI studies one conducted in children and one in elderly analyzing hemispheric connectivity and quality of performance using novel methodologies. Barber et al. (2012) used resting state functional connectivity to examine brain-behavior relationships between motor network connectivity and motor control abilities in typically developing (TD) right-handed children. They found consistent and robust relationships between children's motor abilities and the degree to which connectivity was stronger within the LH motor circuit than it was within the RH circuit. Greater left-lateralized motor circuit connectivity predicted overall better motor ability as reflected in a test of motor skill (PANESS). These results contrast with the findings in a study with young and elderly persons by Davis et al. (2012). This study combined eye-tracking, FMRI, and DTI as well as motor testing to evaluate whether recruitment in the contralateral hemisphere is similar and equally effective in younger and older persons. While in the scanner, participants performed a word matching task where the word pairs were shown unilaterally (i.e., in one visual field) or bilaterally. Results revealed that compared to the younger adults older adults showed greater functional connectivity between left and right PFC, particularly in the bilateral condition. In addition, both behavioral and neural (functional connectivity) measures of cross-hemispheric communication were significantly correlated with DTI measures of callosal integrity in older – but not younger – adults. Overall, these findings indicate that contralateral PFC over-recruitment in older adults is associated with increased left-right PFC connectivity, and furthermore, that this connectivity while dependent on white matter integrity in older adults is beneficial for performance.

Conclusion

The last decade or so has witnessed major methodological advances in imaging and genetics but also in computational analysis. In addition, research paradigms have become increasingly sophisticated lining up multiple approaches as in combining FMRI and DTI or using resting state as the baseline when in addition behavioral indexes are quantified and correlated with indexes of connectivity.

It is fair to say that as a result of this shift in research design a simple or naive structural localizationist approach to addressing questions of asymmetry in brain and body has given way to a developmental and physiological perspective. It appears that asymmetries of body and brain are established quite early and share basic molecular pathways that are evolutionarily well conserved. That said, there are some genes that show altered (asymmetric) expression levels in human brains and play a role in patterning and connectivity providing the brain unlike the viscera lifelong adaptability.

Atomism and Holism: Philosophical Aspects

Michael Esfeld, University of Lausanne, Lausanne, Switzerland

Abstract

In the philosophy of the social sciences, atomism is the view that human beings can be thinking, rational beings independently of social relations. Holism, by contrast, is the view that social relations are essential to human beings insofar as they are thinking, rational beings. This article first provides an overview of different sorts of atomism and holism (see Section Types of Atomism and Holism). It then briefly sketches the historical background of these notions in modern philosophy (Section The Historical Background of Atomism and Holism). The main part is a systematic characterization of atomism and holism (see Section A Characterization of Atomism and Holism) and a summary of the most important arguments for both these positions (see Section Arguments for Atomism and Holism).

Types of Atomism and Holism

If one speaks of atomism or holism, one has to specify with respect to what atomism or holism is claimed. Atomism in one domain can go with holism in another domain, and vice versa. In the social sciences, the discussion on atomism vs. holism focuses on the question of whether social relations with other humans are essential to human nature. The question thus is whether society in the sense of a social community of human, thinking, and acting beings is an atomistic or a holistic system. The question is neither whether a human being can exist in the biological sense without social relations nor whether a human being is dependent on social relations for maintaining a fully satisfactory human life. The point at issue is whether a human being is dependent on social relations to other humans insofar as he or she is a thinking, rational being. Since, on most accounts, thought in the full sense of the term as exhibited by adult human beings is tied to rationality constraints and since rational agency, including moral agency, presupposes thought, the point at issue can be formulated thus: Are social relations necessary for a human being to have thoughts with a determinate conceptual content? Social atomism is the thesis that an individual considered in isolation can have thoughts with a determinate conceptual content. Social holism, by contrast, is the thesis that social relations are essential for a human being in order to have thoughts with a determinate conceptual content. Social holism thereby implies that having thoughts is tied to speaking a public language; social atomism does not have such an implication.

The discussion on atomism vs. holism concerns not only the conditions under which humans can have thoughts; it extends also to aspects of thoughts. The most important issue in this respect is the question of whether meaning is atomistic or holistic. Semantic atomism is the thesis that each thought or sentence has a meaning independently of other thoughts or sentences. Semantic holism, in reverse, is the thesis that the meaning of a thought or a sentence consists in its inferential relations to other thoughts or sentences in a system of thoughts, a theory, etc. There is a middle position, namely semantic molecularism. This is the thesis that only some particular inferential relations to other thoughts or sentences, most prominently the analytic ones, constitute the meaning of a thought or a sentence.

Atomism and holism are put forward with respect to further aspects of thoughts. Confirmation atomism is the thesis that thoughts or sentences can be empirically confirmed or disconfirmed one by one. Confirmation holism, by contrast, is the thesis that only a whole system of thoughts or a whole theory can be confirmed or disconfirmed by experience. Consequently, if a conflict between theory and experience occurs, there are several possibilities for adapting the theory to experience. Justification atomism is the thesis that there are some thoughts or sentences that can be justified without referring to other thoughts or sentences. These thoughts or sentences are the foundation of knowledge. Justification atomism is, therefore, known as foundationalism. Justification holism, by contrast, is the thesis that the justification of any thought or sentence consists in relations to other thoughts or sentences. Justification holism is, therefore, known as coherentism: the justification of a thought or a sentence is given by its being integrated into a coherent system of thoughts or sentences. Although there are arguments that link all these sorts of atomism or holism together, endorsing any one sort of atomism or holism does not logically commit one to endorse any other sort of atomism or holism as well.

The Historical Background of Atomism and Holism

The issue of atomism vs. holism in the social sciences is linked closely with philosophical reactions to what is perceived as the methodology of modern natural science. Thus, social atomism starts when Hobbes applies the method of physical science to social science. Hobbes – in contrast to, for instance, Gassendi – is not a physical atomist: he does not commit himself to the thesis that there are smallest, indivisible bodies that have a few basic properties such as position and motion and of which every complex body is composed (*De corpore/Of Body*, Chap. 15, Sect. 2, Chap. 27, Sect. 1). However, he transfers to the social sciences the method of (1) dividing a complex system up into its constituent parts, (2) considering the parts and their properties in isolation from each other, and (3) understanding the nature and function of a complex system on the basis of the properties of its constituent parts considered in isolation (*De cive/Of the Citizen*, Preface). Hobbes is famous for applying this method to

political science. He thereby commits himself to social atomism: in his political philosophy, he presupposes individuals each of whom is a thinking, rational being independently of the other ones (*De cive*/*Of the Citizen*, Chap. 8, Sect. 1). He reconstructs social and political relations on that basis.

Despite the widespread acceptance of the sketched methodology of the natural sciences as a paradigm for philosophy, holism is proposed as an ontology in early modern philosophy. Most prominently, Spinoza maintains in his *Ethics* that there is only one substance and that everything is a way of being (a mode) of that substance. However, it is only when the supposition that the methodology of physical science is a paradigm for philosophy is challenged in romanticism and its predecessors that social holism emerges as an option. This development is linked with a focus on language and the thesis that language is essential to thought. Thus, for instance, Herder claims (1) that thought is tied to language and (2) that language is tied to social relations. Consequently, he comes to the conclusion that a human can be a thinking being only in virtue of social relations to other humans (see, in particular, *Abhandlung über den Ursprung der Sprache*; partial English translation in Herder, 1993 and see Spencer, 1996). Hegel systematizes this conception and integrates it into his holistic ontology according to which the world is the dialectical development of a spiritual substance. He goes as far as considering individual thinking beings as accidents of a collective substance (for instance, *Grundlinien der Philosophie des Rechts*, Sect. 156; English translation Hegel, 1991). He can be seen as thereby transforming social holism into collectivism.

Social holism in the romanticists is part of their reaction against conceiving philosophy on the model of the methodology of the physical sciences. But the romanticists do not go as far as developing a proper methodology for the social sciences. It is only from the beginning of the twentieth century on that social holism is proposed as a proper methodology for the social sciences. Most prominent in that respect are the works of Durkheim (1927) and Mead (1934). This development again links up with a development in the natural sciences, namely the emergence of systems theory. Systems theory seeks to understand a system on the basis of its constituent parts – but not on the basis of properties that these parts have independently of each other; on the contrary, systems theory sets out to understand a complex system on the basis of the relations into which its constituent parts enter (von Bertalanffy, 1968). Applied to social systems, systems theory can therefore lead to social holism. Moreover, as regards physics, it is claimed that atomism is replaced with a comprehensive holism in our description of the microphysical level consequent upon quantum theory, in the sense that certain relations rather than intrinsic properties are characteristic of fundamental physical systems. This view is worked out in the position known as ontic structural realism in current philosophy of science (Ladyman and Ross, 2007). However, this holism has – as yet? – nearly no repercussions for the social sciences (but see Wagner, 2012).

A Characterization of Atomism and Holism

Both atomism and holism, taken in a general sense, are claims about complex systems in which constituent parts can be distinguished. Having constituent parts is not sufficient for something to be an atomistic system. In reverse, there is no reason to recognize something that does not admit of parts as a holistic system; such a thing would rather be an atom in the literal sense. Both atomism and holism therefore presuppose the analysis of a complex system in terms of parts. For a characterization of atomism in opposition to holism, it is crucial to consider (1) the sort of independence or dependence that holds among the parts and (2) the properties of the parts with respect to which that sort of independence or dependence holds.

Relations of causal dependence among the parts of a complex system are not sufficient to settle the issue of atomism vs. holism, even if they are complicated relations of mutual or circular causal dependence. No one denies that the development of thought and rationality in a human being causally depends on the social environment and that these social relations can be complex ones of mutual and circular causal dependence. But this commonplace does not amount to a refutation of social atomism and an argument for social holism, on pain of trivializing social holism and turning social atomism into an obviously wrong-headed position.

It is, therefore, appropriate to focus on whether or not there are relations of ontological dependence among the parts of a complex system. Ontological dependence is about something depending for its very existence on the existence of some other thing. Two sorts can be distinguished. (1) If an individual *a* cannot exist unless there is a particular individual *b*, then we have a case of rigid ontological dependence. (2) If there can be no individual of a certain kind unless there is some other individual of a certain kind, then we have a case of generic ontological dependence (Simons, 1987, Chap. 8.3; Correia, 2008). The issue of atomism vs. holism is about generic ontological dependence among the parts of a complex system. The holist claims that some social environment is necessary for thought, but not that it has to be, say, one's family, or one's tribe.

According to the standard account of modal sentences in today's philosophy, the necessity that ontological dependence implies is to be analyzed in terms of possible worlds. One can claim that the necessity is metaphysical and thus concerns all possible worlds. But one does not have to go as far as that: one can restrict the scope of ontological dependence so that it applies, for instance, only to all physically possible worlds, i.e., all those worlds in which the same physical laws hold as in our world. Consequently, one can take the following position: Social atomism or social holism applies only to human thinking beings, i.e., to those who share a human nature and who are subject to the physical and biological laws of our world. One thereby refuses to commit oneself as to whether or not in the imagined case of Martians, who are thinking beings, but who do not have a human nature, social relations are necessary for thought. Hence, one can conceive social atomism or social holism in such a way that these positions formulate a conceptual necessity about all possible thinking beings; or one can restrict these positions in such a way that they apply only to us humans.

When it comes to atomism vs. holism, we can further specify generic ontological dependence: (1) We are interested in generic ontological dependence as a symmetric relation, for we are inquiring into the sort of dependence that captures the way in which the parts of a holistic system depend on each other. (2) In

cases such as social atomism vs. social holism and atomism vs. holism with respect to meaning, confirmation, or justification of thoughts, generic ontological dependence concerns the dependence of things of one sort on there being other things of the same sort (Fodor and Lepore, 1992, pp. 1–2). In social atomism vs. social holism, the question is whether there have to be other human thinking beings if there is one human thinking being. This point does, however, not apply to all cases of holism: if an organism is a holistic system, then something that is a heart is not ontologically dependent on there being other hearts, but on there being blood, kidneys, etc.

Most importantly, (3) the issue of atomism vs. holism can be formulated in a more fine-grained way than being about generic ontological dependence that concerns the existence as such of the parts of the kind of systems in which we are interested. The issue is about generic ontological dependence among the parts of a complex system with respect to certain of their properties. The claim of social holism is not that a human being cannot exist unless there are other humans. The claim is that a human being is ontologically dependent on social relations to other humans with respect to the property of thought and rationality, i.e., insofar as it is a thinking, rational being. Otherwise, social holism would be an absurd position: it would have to claim either that a baby already has thoughts in the full sense of the term, or that a baby and an adult cannot be the same individual. Thus, for a characterization of atomism vs. holism, it is necessary to filter out properties for which it is a substantial issue whether or not the parts of a complex system are ontologically dependent on each other with respect to these properties.

For every system of a qualitative kind, there is a family of nondisjunctive, qualitative properties which make something a system of the kind in question. Such a family of properties can include both nonrelational and relational properties. Something is a system of the kind *S* if and only if it has all – or by far most of all – the properties that make something an *S*. For instance, if something is a grain of sand, a certain molecular structure as well as a shape, size, and mass within a certain margin count among the family of properties that make something a grain of sand. Applied to the parts of an *S*, this notion is to say: There is a family of qualitative, nondisjunctive properties that make something a part of an *S* – in case the thing is arranged with other things in a suitable way. Having all or nearly all the properties that belong to such a family of properties is a necessary condition for something to be a part of an *S*; it is a sufficient condition in conjunction with the condition of a suitable arrangement with other things.

The condition of a suitable arrangement has to be imposed in order to exclude those properties for which it is trivial that something can have them only by being part of a complex system. For instance, a human being can exercise a social role – such as being a judge, or being a salesman – only by being part of a social system. Social roles are arrangement properties. Pointing out social roles is not sufficient to make a case for social holism, again on pain of trivializing social holism and turning social atomism into an obviously wrong-headed position. The question is whether properties that are the prerequisite for exercising a social role – such as the property of thought and rationality in the sense of having thoughts with a determinate conceptual content – require social relations. By excluding from the mentioned family of properties those relational properties in which the arrangement with other things consists, we pick out the properties that underlie the arrangement. There is a substantial case of holism if and only if these properties are relational as well – in the sense that one thing can have these properties only if there are other things together with which this thing is arranged in such a way that there is an *S*. Consequently, there is a substantial case of atomism if and only if something can have these properties independently of whether or not there are other things with which this thing is arranged in such a way that there is an *S*.

The issue of atomism vs. holism can now be characterized as follows: consider a system of the kind *S* and its constituent parts. For every constituent part of an *S*, there is a family of qualitative, nondisjunctive properties that make something a constituent part of an *S* provided that there is a suitable arrangement. The issue whether or not an *S* is holistic depends on whether or not the following condition is satisfied by all the things which are its constituent parts: With respect to some of the properties that belong to such a family of properties, a thing is ontologically dependent in a generic way on there being other things together with which it is arranged in such a way that there is an *S* (Esfeld, 1998). If there are some properties that satisfy this condition, the system is holistic with respect to these properties. With respect to all those properties within the mentioned family of properties that do not satisfy this condition, the system is atomistic.

This is a fine-grained characterization of atomism and holism: One and the same system can be atomistic in regard to some properties, but holistic in regard to other properties. Apart from the above-mentioned variable of the scope of ontological dependence, there are two variables with respect to the properties that atomism or holism concerns: (1) the number of these properties: for instance, in the case of a system of thoughts, one can maintain that holism not only concerns both confirmation and meaning, but also that it concerns only confirmation; one can hence claim that a system of thoughts is a holistic system with respect to confirmation, but an atomistic system with respect to meaning (Fodor and Lepore, 1992, Chap. 2); (2) the importance of these properties: all the properties that atomism or holism concerns are important in that they belong to the family of properties which make something a constituent part of a system *S* provided that there is a suitable arrangement. Nonetheless, the properties that are touched by atomism or holism can be more or less important as far as the identity of the system and its constituents is concerned. For instance, in the case of a thinking human being who is a constituent part of a social community, the property of having thoughts is not necessary for the identity of the human being concerned. If a human being develops from a baby into a normal adult and then goes insane, she nevertheless remains the same human being throughout this development. By contrast, consider the case of atomism or holism of thought with respect to meaning: If a constituent of a system of thoughts changes its meaning, it is no longer the same thought.

The outlined characterization makes clear that the issue of atomism vs. holism is distinct from the issue of individualism vs. collectivism. The former issue is about the way in which the constituent parts of a complex system are interrelated with each other. It is noncommittal on the issue of whether or not there are forces or regularities by means of which a whole influences

the behavior of its parts. Collectivism is the claim that there are such social forces; this claim is not implied by social holism. Social holism can go with individualism: It can be conceived as being about the requirements under which a human being can develop into an individual personality (Pettit, 1993, Chaps. 3, 4); *see* Individualism versus Collectivism: Philosophical Aspects.

Arguments for Atomism and Holism

The main argument for social holism and the main challenge that social atomism has to meet stem from the work of the later Wittgenstein, in particular the *Philosophical Investigations* and the interpretation of that work by Kripke (1982). Kripke sets out what is known as the problem of rule-following, i.e., the problem of how the thoughts of finite thinking beings can have a determinate conceptual content. He raises the following issue: Any finite sequence of examples or of actions including linguistic actions of persons can in principle be described in terms of infinitely many different rules. Consequently, (1) there are infinitely many possible ways of continuing any such sequence in any new situation, and (2) for any new situation, it is not determined what is the correct way to go on. The problem of rule-following then is this one: What can select for us one of infinitely many rules so that for us one way of going on is singled out as the correct one? *See* Meaning and Rule Following.

According to Kripke's interpretation of Wittgenstein, to the extent that there is rule-following at all, social interactions are necessary in order to (1) select for a person one of infinitely many meanings in a finite sequence of examples or of actions and (2) enable a person to have a distinction between correct and incorrect rule-following at their disposal. This is the main argument for social holism. This argument speaks against the attempt to reduce the description of thoughts to a description in terms of the natural sciences.

There are two main ways in which social holism can be spelled out. One possibility is to conceive social holism in terms of an asymmetric I–we relation: An individual becomes a thinking being by being integrated into a social community. The members of the community assess the actions of the individual according to what they take to be fit and proper. In this case, norms are reduced to social facts: The fact of community approval or disapproval is identified with correctness or incorrectness. The actions on which the members of a community agree are not themselves liable to an assessment as being correct or incorrect. This position consequently is a social relativism. Its most extreme version is a radical meaning finitism that considers the extension of a concept only to be determined insofar as factual communal agreement reaches at a time (Bloor, 1997, Chap. 2).

The other possibility is to conceive social holism in terms of symmetric I–thou relations between individuals assessing each other's actions as correct or incorrect. This conception does not have to identify norms with social facts. Instead, it can regard these assessments as an open-ended process. Each normative attitude of taking something to be correct or incorrect, including those attitudes that are shared by all the members of a community at a time, can be challenged as not being correct. This position makes it possible to conceive the normative attitudes of taking something to be correct or incorrect as being responsive and responsible to the way the world is. It thus combines social holism with a realism (Pettit, 1993, Chap. 4; Brandom, 1994, Chaps. 1, 8; Hattiangadi, 2007).

If one intends to defend social atomism, one has to meet the challenge that Kripke poses. Two strategies can be distinguished. One strategy is to make a case for meanings as entities beyond the physical, including persons and their interactions (Katz, 1990, Chaps. 2–4). Having thoughts with a determinate conceptual content then does not depend on social relations, but on standing in an appropriate relation to such entities, i.e., grasping meanings. The other, most widespread strategy is to argue for some sort of a naturalization of semantics, i.e., an account of meaning in the vocabulary of the natural sciences. One then has to show how an account in terms of dispositions to behavior can solve both the infinity and the normativity problem that Kripke raises. Prominent proposals are an account in terms of computation (Miscevic, 1996), a teleofunctional account (Millikan, 2005), and an account within an ontology of causal, dispositional properties in general (Heil, 2003, Chap. 18). According to these accounts, certain dispositions that each human being has considered in isolation from other human beings are sufficient for a human being to have thoughts with a determinate conceptual content – although, of course, social relations influence the way in which the thoughts of a person develop.

Social holism is a social externalism: The thoughts of a person are externally individuated, namely by the person's relations to her social environment. Social atomism, by contrast, is an internalism: The thoughts of a person are individuated by factors that are internal to that person, such as her dispositions to behavior. Independently of Kripke's argument, Burge (1979) makes a case for social externalism by claiming that the meaning of the thoughts of a person depends on the way in which the terms in which that person expresses her thoughts are used in her social community. Burge's method is to develop thought experiments in which he keeps all the factors that are internal to a person fixed and varies the social environment. He thereby intends to show that the social environment enters into fixing the meaning of the thoughts of a person. Burge's argument fits into the method that dominates the discussion on externalism in general. A common reply to the externalist arguments is to distinguish between narrow and wide content of thoughts: The externalist argument is granted as far as wide content is concerned. But it is claimed that there is a narrow content of thoughts which is internally individuated and which is all that is needed to explain behavior. Thus, social atomism is vindicated as far as narrow content is concerned.

Social holism can be combined with semantic holism if one maintains that social relations determine a content for a thought of one type only by determining a content for other types of thoughts as well that constitute an inferential context for the thought in question (Brandom, 1994; Weiss et al., 2010). However, one does not have to combine semantic holism in form of an inferential semantics with social holism. The most widespread version of semantic holism is an inferential semantics applied to narrow content (Block, 1986). Hence, a semantic holism can go with a social atomism. Moreover, subsequent to the influential criticism of semantic holism by Fodor and Lepore (1992), arguments for semantic

atomism as well as semantic molecularism have gathered new momentum (Devitt, 1995).

By contrast, holism with respect to the confirmation of thoughts or sentences is widely accepted owing to Quine (1951). Confirmation holism is one of the backgrounds of the view of science of Kuhn (1962), which is also influential in the social sciences. It is in dispute to what extent confirmation holism and Kuhn's view of science lend support to social relativism. Because of the presumed relativistic consequences, Quine (1969) rejects Kuhn's view of science and excludes observation sentences from both confirmation and semantic holism, defending atomism with respect to these sentences.

Abstract

This article presents an overview of ethological attachment theory as conceptualized by John Bowlby, characterizing the development of attachment relationships during infancy as biologically preprogrammed capacity. It depicts various empirical approaches to measure differences in attachment relationships and presents the ongoing scientific discussion on the psychobiological processes underlying different attachment organizations. The end of the article summarizes major challenges to the original formulation of attachment theory posed by cultural psychology, anthropology, and sociobiology, which led to innovations of the theory, generating a context-informed approach to attachment.

Introduction: Attachment Theory

The psychoanalyst and pediatrician John Bowlby (1990[†]) is considered the founder of attachment theory. After World War II, he practiced at the children's ward at Tavistock Clinic in England, when he was asked to provide a report on behalf of the World Health Organization on the situation of homeless and orphaned children in this period of time. In this report, he described the effects of childhood separation and deprivation he observed on a daily basis and postulated that caregiving environments influence the mental health of children. He argued that psychology was in need of a theory that actually accounts for the developmental consequences of early socioemotional experiences. In the following years, his ideas turned into attachment theory, which became one of the most influential theories of developmental psychology to this day (Bowlby, 1969, 1973, 1980).

Situating Attachment Theory: Sociohistorical Circumstances

Until the 1960s, best practice for child rearing stipulated providing adequate food and hygiene for babies, while keeping physical contact at a minimum to diminish the likelihood of the transmission of diseases, and to not spoil a child (Pauen, 2006). Preverbal infants were considered as creatures without feelings, and emotions between adults and infants did not play a role. Parental guidebooks from the first half of the twentieth century recommended to "place the child in a separate room in which it remains alone" (Haarer, quoted by Chamberlain, 2000: p. 26). The devastating consequences of this child care concept became obvious particularly in orphanages or hospitals where children often showed massive socioemotional disturbances. The observation of these developmental consequences made Bowlby challenge the prevailing principles of child care.

The Roots of Attachment Theory

Drawing on evolutionary theory as outlined by Charles Darwin who stated that natural selection favored behavioral systems, which proved adaptive (Darwin, 1860), Bowlby assumed that the attachment system also had *evolutionary roots*. According to Bowlby, attachment increased the likelihood of infant survival in the environment in which our ancestors lived ('environment of evolutionary adaptedness,' Bowlby, 1969). Children displaying attachment behaviors such as crying or following were more likely to stay in contact with their caregivers, and thereby heightened their chances of survival compared to infants not showing attachment behaviors. As attachment increased individuals' survival and reproduction rates, it became consolidated in the human genome.

Bowlby also incorporated findings from *ethological research*: The phenomenon of imprinting observable in animals reminded Bowlby of attachment behaviors in humans. Imprinting is known in ethology as an irreversible form of learning (Lorenz, 1943): During a relatively short, genetically determined time period ('critical period'), stimulus-response patterns become permanently incorporated in the behavioral repertoire of animals. Lorenz demonstrated that incubator-hatched geese would imprint on the first stimulus they saw within the first hours after hatching, henceforward following this stimulus unconditionally. In natural environments, this stimulus is typically the mother, but in experiments, Lorenz could show that the goslings would also imprint on him. Bowlby assumed that there is a similar mechanism at work for attachment formation in humans: there is a critical period for humans to develop attachments (i.e., the first year of life) when children rely on innate reflexive behaviors (e.g., smiling, crying, following) to form attachments. However, Bowlby assumed that in humans, fixed reflexive behaviors turned into '*open genetic programs*' in the course of phylogeny, and are thereby – within certain biological limitations – way more flexible. In terms of attachment, this means that the shape of attachment relationships does not only depend on genetic programs, but also on various environmental factors. Thereby the attachment system is flexible enough to adapt to different conditions.

In the 1950s, Harry Harlow, a *primate researcher*, explored the basics of mother–child love in primates in the United States and could disprove the assumption of learning theorists that attachment is the result of classical conditioning (Harlow, 1958/1997). He raised young rhesus monkeys with two 'surrogate mothers': one dummy mother was made of wire and provided milk for the young monkeys, another dummy

 http://dx.doi.org/10.1016/B978-0-08-097086-8.23166-8

mother was covered with cloth, but provided no milk. Harlow could show in his experiments that the monkeys stayed with the lactating wire dummy mother only for the time of feeding, but otherwise cuddled with the fabric-covered dummy mother. Put under stress, the young monkeys always fled to the fabric-covered dummy mother. Harlow thereby proved that a cuddly dummy mother is emotionally more satisfying for a young rhesus monkey than a wiry food source.

Due to his training in *psychoanalysis*, Bowlby was well aware of the importance of the first years of life for later development. However, unlike Freud who believed that drives determine our psyche from early childhood on, Bowlby thought that early socioemotional experiences influence the future development of children. Children do not simply mature to become a person: they are shaped by their early social environment, especially by interactions with their main caregivers.

As attachments develop in interactions, Bowlby used *systems theory* to describe the dyadic and dynamic processes of relationship formation (Bischof, 1975). He conceptualized attachment relationships as feedback loops with the goal of establishing physical and/or psychological safety of the child. If stressed, the child displays attachment behaviors, which trigger caregiving behaviors in parents; these caregiving behaviors help the child to regain physical and/or psychological safety. Safety in the presence of a protective caregiver allows a child to freely explore the environment. The attachment system thus faces a complementary behavioral system: the '*exploratory system*.' The two systems function antagonistically: if one is active, the other is disabled and vice versa.

Bowlby's Concept of Attachment

Bowlby defined attachment as an emotional bond – '*a child's tie to his mother*' – that develops during the first year of life (Bowlby, 1969). He assumed that each infant has an innate attachment motivation, which is equal to other basic human needs, e.g., hunger or thirst. This natural attachment motivation evokes attachment behaviors that help to establish proximity to caregivers. The actual behaviors vary with age and motor abilities of the child: smiling, crying, clinging, crawling, and following are some of them. Caregivers usually react intuitively to these attachment behaviors with nurturing or caregiving behaviors. According to Bowlby (1969), attachment develops in four phases:

- During the first 6 weeks of life ('the preattachment period'), infants make little distinctions between persons, who can be exchanged almost arbitrarily.
- In the following 6 months ('attachment in the making'), infants direct signals to particular persons and start showing preferences for these persons.
- Once children are able to move, they actively seek closeness to caregiver(s), showing distinct attachment behaviors ('clear-cut attachment'). With 12 months, individual attachment relationships originated in the context of daily interactions, and children developed expectations about the accessibility and reliability of their caregiver(s) in case of insecurity and danger.
- From about the age of three, children form a more complex partnership ('goal-corrected partnership') with their caregiver(s) on the basis that they begin to see others as independent persons with own goals and feelings.

Bowlby postulated a hypothetical construct, the so-called internal working model (IWM), in which early attachment experiences are represented as a system of thoughts, memories, beliefs, and expectations about the self and others. IWMs can be defined as: "a set of conscious and/or unconscious rules for the organization of information relevant to attachment and for obtaining or limiting access to that information, that is, to information regarding attachment-related experiences, feelings, and ideations" (Main et al., 1985: pp. 66–67). Accordingly, experiences with a reliable mother should result in a positive IWM of self and caregiver, experiences with an unpredictable, unreliable attachment figure in a negative IWM. Though IWMs are formed during the first year of life, attachment theory assumes that they fundamentally influence our future socioemotional development and remain influential over the life span.

Empirical Approaches to Attachment

Mary Ainsworth and her colleagues made attachment theory accessible to empirical research (Ainsworth, 1967; Ainsworth et al., 1978). During a stay in Uganda, Africa, Ainsworth observed individual differences in mother–infant pairs: Separated from their mothers and in the presence of the strange researcher, the majority of children showed distinct attachment behaviors, a second group of children displayed exaggerated or inconsistent attachment behaviors and a third group of children did not show any attachment behaviors at all. She called these three groups of children 'securely attached,' 'insecurely attached,' and 'nonattached,' respectively.

Back in the United States, Ainsworth wanted to replicate her findings with families from Baltimore, but realized that 1-year-old US children were not alarmed when separated from their mothers; obviously, the US children were accustomed to be temporarily separated from their mothers and also to the presence of unfamiliar people in their homes. Thus, Ainsworth invited mothers and their children to a 'foreign' laboratory at the university, creating the paradigm of the '*strange situation procedure*' (SSP), a mini drama with fixed sequences to elicit attachment and exploratory behaviors in children (Ainsworth et al., 1978). During the SSP, the child is exposed to seven 3-min episodes that become increasingly stressful: In the first episode, mother and child are alone in the room; in the second episode, a stranger appears and starts to interact with the child; in the third episode, the child is left alone with the stranger; in the fourth episode, the mother returns and the stranger leaves; in the fifth episode, the mother exits for the second time, leaving the child completely alone; in the sixth episode, the stranger returns; and in the seventh episode, the mother finally returns. On the basis of their separation and reunion behaviors with the mother and their interaction with the stranger, children are classified into the four categories:

- *Securely attached children* (*B*) show their emotions openly: They articulate their fear and sadness in the separation situation, show their joy and elation in the reunion with

their mothers, and calm down quickly. They are able to use the presence of the mother as a 'secure base,' from which they explore the environment and interact with the stranger.

- *Insecure–avoidant children* (*A*) do not show their emotions openly but avoid expressions of attachment. They seem unimpressed by the separation from the mother, and ignore their mother in the reunion situation. Avoidant children prefer to interact with the stranger and the interactions are predominated by exploratory behaviors.
- *Insecure–ambivalent children* (*C*) show attachment behaviors constantly with anger being the dominant emotion. They seem overwhelmed by the pain of separation, do not calm down in the reunion with the mother and hardly interact with the stranger, even in the presence of the mother.
- *Disorganized children* (*D*) represent a fourth category that was added by Main and Solomon in the 1980s (Main and Solomon, 1986). Children in this group show bizarre behaviors and repetitive movements. Disorganized attachment is conceptualized as the lack of a coherent behavioral strategy for dealing with stress.

Using the SSP, Ainsworth and colleagues classified 106 US children, and the distributional pattern of 66% secure, 22% avoidant, and 12% ambivalent children is referred to as the 'American Standard distribution' (Ainsworth et al., 1978). Moreover, Ainsworth found correlations between the attachment security of children and the quality of their mothers' interactive behaviors: Children with mothers who responded sensitively to their children's needs were more likely to be securely attached, whereas children with less sensitive mothers were more likely to be insecurely attached. The quality of maternal interactive behavior was defined by Ainsworth et al. (1978) as *maternal sensitivity* and captured the mothers' ability to

- perceive the child's signals,
- interpret the signals correctly,
- respond adequately, and
- respond promptly.

The correlations between maternal sensitivity and infant attachment organization demonstrate the plasticity of the attachment system: secure children have learned that their signals are perceived and interpreted correctly, so they rely on help from their caregiver and communicate their feelings. Avoidant children have learned to suppress their emotions, as the mothers of these children are stressed by negative signals. Insecure–ambivalent children have mothers who are not consistent in their behaviors; this unpredictability puts children in the situation to have a notoriously activated attachment system. Disorganized children lack a coherent strategy altogether, which is often the product of abuse through the caregiver. In these cases, the attachment figure, who is supposed to provide protection, becomes a threat, which puts the child in a 'double bind situation' with no way out.

The *core assumptions of attachment theory* as established by Bowlby and Ainsworth, can be summarized as follows:

1. *Universality*: All healthy newborns develop attachment relationships with their caregiver(s) during their first year of life.
2. *Normativity*: The majority of children develop secure attachment relationships; insecure attachment patterns are less frequent.
3. *Sensititvity*: Maternal sensitivity is an important antecedent for attachment security.
4. *Competence*: Securely attached children are more competent in the solution of further development tasks.

Psychobiology of Attachment

The attachment system aims at maintaining or restoring homeostasis in the human organism (Bowlby, 1969). On the behavioral level, being reunited with the caregiver serves this goal. On the biological level, physiological systems also aim at the maintenance of homeostasis; here regulation takes place continuously, e.g., by increases/decreases in blood pressure or heart rates. The attachment system and the physiological systems are primarily independent, but can be activated together, e.g., during a stress response. From the 1980s on, the interplay of these two systems has been investigated by various disciplines, such as neuroscience, biology, and neurophysiology.

In humans, the activation of two physiological systems during a stress response can be observed noninvasively: The cardiovascular system responds to changes in heart rate, which can be measured easily (Spangler and Schieche, 1998); the pituitary adrenocortical system releases the stress hormone cortisol, which is detectable after a brief time delay in saliva (Chryssanthopoulou et al., 2005). Cortisol became especially prominent in attachment research because cortisol measurements can be used before and after stressful situations, thereby indicating the degree of a stress experience (e.g., Gunnar, 2005). To date, empirical findings concerning the interplay of attachment behavioral strategies and adrenocortical activation produced no clear picture yet. Instead, two different theoretical models are discussed in the literature: the 'coping model' and the 'arousal model.'

The coping model assumes that different attachment qualities equip children with different coping strategies for regulating their emotions. This model is supported by studies (e.g., Spangler and Grossmann, 1993) reporting that infants with insecure attachments – especially those with disorganized attachments – showed higher cortisol levels following the SSP, which is interpreted as proving the suitability of the secure attachment strategy to deal with stress. In contrast, the arousal model assumes that only infants exhibiting behavioral stress in terms of crying or negative emotions have a heightened adrenocortical activity. This model is supported by studies that reported a fundamental increase of adrenocortical activation in ambivalent and disorganized infants (e.g., Hertsgaard et al., 1995). However, many studies report no differences in the adrenocortical response between the insecure attachment groups (e.g., Gunnar et al., 1996), or found cortisol increases only in insecure infants who were additionally characterized by behavioral inhibition (e.g., Nachmias and Gunnar, 1996). These studies suggest that both temperamental characteristics and attachment quality may influence the function of the adrenocortical system, whereby attachment security may function as a moderator for the activity of the hypothalamic-pituitary-adrenal (HPA) system.

Although the biobehavioral organization of attachment is not completely understood yet, it is obvious that the interplay of the behavioral and the adrenocortical system differs between the attachment groups. Research has revealed the immense complexity of the psychobiology of attachment and future research might provide definite answers to the question concerning the mechanisms of the biobehavioral organization of attachment.

Intergenerational Continuity of Attachment

Another unsolved question is if and how attachment styles are passed over generations. Van IJzendoorn (1995) proposes in the so-called *transmission model* that parental behaviors have their roots in childhood experiences. Thus, securely attached children should become better parents (Main, 1990). However, while children's IWMs can be assessed in the Strange Situation on a behavioral level, the assessment of adults' IWMs requires a move to the level of representation, because a direct correspondence between behavior and mental structures is no longer a given in adulthood. Therefore, the '*adult attachment interview*' (AAI; Main et al., 1985; Main and Goldwyn, 1998), a semistructured interview, was devised by with the idea to assess adults' state of mind with respect to attachment as expressed in discourse about early relationships. Interestingly, the content of these autobiographical memories did not become the main indicator for an adult's attachment classification; instead, communication styles proved more illuminative, especially the concept of coherence. Coherence is based on the four the so-called Gricean maxims: be truthful and have evidence for what you say (*quality*); be succinct, yet complete (*quantity*); be relevant (*relevance*); and be clear, brief, and orderly (*manner*). During the AAI, an interviewee is faced with the task of producing and reflecting upon memories related to attachment while maintaining a coherent discourse with the interviewer. AAI classifications refer to differences in discourse style, four discourse patterns have been identified:

- *Secure–autonomous* adults (*F*) provide a discourse that is open and coherent, presenting even difficult attachment experiences in clear and vivid ways. The discourse shows no contradictions, the focus is on the conversation and interviewees show a rich use of language.
- *Dismissing* adults (*D*) provide extremely brief interviews that are characterized by striking contradictions in the interviewee's discourse about early attachments, with generalized representations of history being unsupported. A strong idealization of caretakers is common, along with contradictory memories of events.
- *Preoccupied* adults (*E*) talk excessively long and include information that is irrelevant to the discourse. Interviewees are not able to describe their attachment biography coherently or to move beyond an excessive preoccupation with attachment relationships. Their discourse is full of passive speech, unfinished sentences, and vague expressions.
- *Unresolved* adults (*U*) show lapses in reasoning, especially when discussing traumatic events involving loss or abuse. For example, they may indicate the belief that a dead person is still alive, lapse into prolonged silences, or enter a trancelike state of mind.

Theoretically, the AAI was supposed to shed light on the intergenerational transmission of attachment, e.g., adults with a secure–autonomous state of mind should be the better, i.e., more sensitive parents; however, meta-analyses could not prove these assumptions empirically (Van IJzendoorn, 1995; De Wolff and Van IJzendoorn, 1997). Instead, it became obvious that other aspects besides sensitivity play an important role in the development of attachment security (Madigan et al., 2006). Measures capturing dyadic dimensions of caregiver–child interactions, e.g., the 'scale of reciprocity' (De Wolff and Van IJzendoorn, 1997), and the inclusion of contextual factors, e.g., the family's socioeconomic status or the child's temperament (Belsky and Fearon, 2008) proved informative. Moreover, mentalization concepts were considered a possibility to close to transmission gap. Meins (1997) could show that mothers who were able to verbalize the inner psychological states of their children were likely to have securely attached children. She called this ability of mothers to put themselves into the mental state of the child 'mind-mindedness.' Alike measures, e.g., the 'reflective functioning scale' (Fonagy et al., 1998) capturing a caregiver's ability to reflect the mental state of the child, revealed correlations with the child's attachment security. But though research on attachment increased tremendously, the transmission of attachment cannot be explained entirely. The ongoing discussion in the literature is referred to under the term 'transmission gap' (Van IJzendoorn, 1995).

Methods and Problems of Attachment Research

The buzz around attachment research brought a variety of new tools and methods with it. Besides *behavioral observations* of infants, e.g., using the SSP or the Attachment Q-sort (Waters and Deane, 1985) and *interview procedures* such as the AAI or the Child Attachment Interview (Target et al., 2003), there are mainly two more classes of methods applied in attachment research: Projective methods and questionnaires.

Projective methods use ambivalent material, such as pictures or stories, to elicit unconscious projections. Projections are supposedly influenced by attitudes, motives, and wishes of a person, they can be interpreted by trained evaluators and thereby obtain diagnostic value. Frequently used projection methods are the 'separation anxiety test' (Klagsbrun and Bowlby, 1976; Kaplan, 1987) and the so-called attachment story completion task (Bretherton et al., 2001).

In contrast, *questionnaires* aim at the self-assessment of the subjects. The first questionnaire to assess attachment styles was formulated by Hazan and Shaver (1987). In their 'attachment self-report,' they designed distinctive vignettes for each attachment style and asked their participants to self-assess their attachment style. A variety of different questionnaires was developed over time, e.g., the 'attachment style measure' (Simpson, 1990), the 'adult attachment scale' (Collins and Read, 1990), or the 'adolescent attachment questionnaire' (West et al., 1998).

As attachment research offered more convenient tools of measurement, attachment research became highly attractive for

many researchers, and till today thousands of papers on attachment have been published. However, the empirical study of attachment comprises a serious method problem as different conceptualizations of attachment become apparent in the different methods: Empirically, correlations between attachment patterns identified with different methods are disappointingly low or trivial (e.g., Roisman et al., 2007). This inconsistency of classifications renders it highly unlikely that the different methods capture indeed the same construct. Instead, it indicates a fundamental lack of clarity in the conceptualization of attachment.

Cultural Variations

In Bowlby's original formulation of attachment theory (Bowlby, 1969), an important feature of the attachment system was its flexibility to adapt to various environmental conditions. For children during their first year of life, social experiences with caregivers constitute a major environmental influence. Moreover, the fact that different experiences result in different attachment patterns documents the plasticity of the attachment system nicely. However, cross-cultural studies demonstrated that early social interactions do not only vary on an individual level, but are also strongly influenced by the ecocultural context within which they take place (Keller, 2007): Parents raise children differently in different cultural environments in order to equip them with the necessary competencies to become successful in a specific environment. This also impacts the development of attachment formation.

Early Pitfalls of (Cross-)Cultural Attachment Research

Unfortunately, the majority of cross-cultural studies on attachment did not take culture seriously for many years and instead relied on Ainsworth's paradigm of the SSP, arguing that the procedure itself represents a culture-sensitive method as it was developed by Ainsworth after research in Africa (Van IJzendoorn, 1990; Van IJzendoorn et al., 2006). This assumption proves incorrect as a close examination of Ainsworth's publications reveals that the invention of the SSP resulted from the very fact that one method, namely natural observations during house visits, did not allow the observation of attachment behaviors in both African and American children. The invention of the SSP resulted as a necessary adaptation of observational methods within the African and US contexts. Albeit cultural realities caused the invention of the SSP, it spread worldwide without accounting for cultural differences other than distributional differences in attachment patterns, which were only post hoc explained as cultural differences. The secure attachment pattern was regarded as the optimal attachment strategy everywhere using the circular argument that secure behavior represents the norm because the majority of infants are characterized as securely attached in the SSP worldwide (Van IJzendoorn and Kroonenberg, 1988). The two insecure patterns were both regarded as less optimal coping strategies, and the disorganized pattern as an extremely disadvantageous strategy (DeOliveira et al., 2004; Main and Solomon, 1990).

Mother–Infant Relationships from a Historical and Anthropological Perspective

Today, the intrinsic role of culture in developmental processes is increasingly acknowledged: Culture represents the primary mode of adaptation to the demands of a particular ecocultural context or niche, thereby creating shared cultural practices and shared meaning systems (Greenfield and Keller, 2004; Super and Harkness, 2002). Regarding development, culture can be considered as the necessary software that gives adaptive direction to the neurophysiological hardware, the inherent capacities all newborns possess (LeVine et al., 1994). Consequently, cultural environments and the biological nature of human development are strongly interrelated (Greenfield, 2002). This view also applies to the study of attachment, which brings reinterpretations and innovations.

Data of Ainsworth's original SSP were collected in a distinct Western population, so infants' reactions should be interpreted as reflecting variations of norms of social distance and interpersonal responsiveness of that historical time (LeVine and Norman, 2001); and not as universal norms per se. This sociohistorical perspective clearly challenges the validity of the American Standard distribution as setting a universal benchmark. Similarly, invoking a historical perspective reveals that in former times the phase of infancy did not resemble the ideas of attachment theory about infancy: In the past, mothers were unlikely to pay a lot of attention to their babies, instead, they often relied on a 'wait-and-see' strategy toward the newborn. This strategy was caused by high infant mortality rates that made infant survival unpredictable and early investment in babies uncommon. Moreover, childbirth and breast-feeding physically weakened a mother's health to the point that it threatened maternal survival. Yet a mother was far more important to the family than a baby, maternal health had always primacy to a baby's well-being, which gained infants a marginal status at the very beginning of their lives (Lancy, in press).

There is also vast anthropological evidence that attachment theory's original formulation was more a cultural ideology, not a universally applicable theory (for a summary see LeVine, in press): In non-Western societies, mothers often lack the resources for exclusive caretaking due to a heavy workload and a high number of children, so caregiving is socially distributed and also not an adult responsibility per se (Weisner and Gallimore, 2008). For example, Aka infants and young children in the Central African Republic can be observed to interact with just over 20 caregivers each day, and half of these caregivers invest in intensive forms of caregiving (Meehan, 2009). Similar observations are reported for Beng infants from Cote d'Ivoire (Gottlieb, 2004), for Nso infants from Cameroon (Keller and Otto, 2009; Yovsi, 2003), and for Gusii children from Kenya (LeVine et al., 1994). These insights clearly question the monotropic understanding of relationships that are prevalent in attachment theory's assumptions, but adhere only to Western nuclear families. Alternatively, sociobiologists (e.g., Hrdy, 2005) put forward the so-called cooperative breeding model as the reproductive strategy in ancient human history where alloparents allowed mothers to redistribute the cost of raising offspring (Hrdy, 1999). This view is supported from an evolutionary

viewpoint: living in social units offered advantages such as a lesser probability to be attacked, a better defense against aggressors, and more efficient food acquisition (Voland, 2000). And while nuclear families could survive and reproduce, they were likely to fall short compared to families that can rely on a more extensive network of support (Mace and Sear, 1997, 2006). If our ancestors lived in larger social units, attachment relationships would have developed not only with mothers, but with many social others that served similar functions (Belsky, 1997; Porges, 2003; Trivers, 1996). Multiple diverse attachment relationships may indeed have constituted the reality for most of our ancestors' children.

Culture-Informed Attachment Research

A side effect of using the SSP across different cultural contexts was that researchers sidestepped the big question: *Are attachment processes essentially the same or significantly different across cultures?* The answer to this question seems to be that attachment indeed varies across cultures. Sagi wrote: "the repertoire of attachment behaviors is similar across countries, but the selection of these behaviors is culturally specific" (Sagi, 1990: p. 19). Differences concerning the development of attachment relationships have been found on three different levels: (1) *parental socialization goals*, which vary in accordance with sociocultural environments, (2) inform actual *parenting behaviors* in interactions with infants, and (3) lead to the formation of culture-specific, ideal *attachment strategies in children*.

1. A study focusing on maternal *socialization goals* and perceptions of attachment compared Anglo and Puerto Rican working- and middle-class mothers in the United States (Harwood et al., 1995). Harwood et al. used vignettes of Strange Situation behaviors, revealing that maternal perceptions of desirable and undesirable attachment behaviors differed from the labels given to them by attachment theory. Mothers could prefer behaviors coded as insecure, and disapprove behaviors coded as secure, based on the SSP ratings. Similar results were found with regard to attachment relationships in the Japanese culture where the indigenous Japanese concept of relatedness, *amae*, involves insecure–ambivalent behaviors (Rothbaum and Kakinuma, 2004). Also, Cameroonian Nso mothers were found to dislike the idea of developing an exclusive relationship with their infants (Otto, 2008). Nso children crying openly upon being separated from the mother were regarded as naughty; in contrast, mothers valued expressionless infants. Nso mothers trained their children to be used to others because "*one mother alone cannot take care of an infant*."
2. Actual *maternal behaviors* toward infants vary across cultures: Whereas sensitivity may be regarded as optimal parenting and represent a precursor of attachment security in the Western world, maternal behavioral strategies look drastically different in non-Western cultures: For example, Cameroonian Nso mothers prefer a controlling parenting style that would be regarded as intrusive parenting following attachment theory (Yovsi et al., 2009). Nso mothers consider themselves as experts in raising their children, so they actively structure interactions, which often includes interfering with the babies' activities. To consider babies as persons with their own will and their own mind is unheard of in many non-Western context, e.g., in the Cameroonian Nso, but only then does it make sense to address them in a mind-minded way as do Western parents. Societies in the Pacific represent an extreme as they claim a fundamental unknowability of other minds in general, which is referred to as the 'opacity doctrine' by anthropologists (e.g., Duranti, 2008; Schieffelin, 2008). In this case, talking to babies to verbalize the baby's state of mind or emotions does not make any sense. Furthermore, research has shown that mothers are attuned differentially to positive or negative signals across cultures (Keller et al., 2008), so that today many researchers arrived at the conclusion that maternal sensitivity is expressed in cultural specific ways, depending on a variety of ecological and cultural constraints and incentives (Thompson, 1997; Thompson et al., 2005).
3. The investigation of *children's attachment strategies* across cultures needs an emic approach, but only few studies to date did not rely on the SSP to assess children's actual attachment patterns. For the Cameroonian Nso, the ideal strategy is characterized by the absence of emotional expressions and an adaptation to the caregiver structuring the interaction: 1-year-old Nso children were expressionless even when approached and picked up by a stranger (Otto, 2008), and they readily followed the stranger's initiatives (Otto, in press). Calm and inexpressive infants were found highly valued in other cultures as well, e.g., in a rural Iranian community (Friedl, 1997) or in the Yucatec Mayan community (Howrigan, 1988). These cultures are characterized by a heavy workload of mothers combined with high fertility rates, which forces mothers to rely on multiple caregiving arrangements. As expressionless infants can easily be taken care of by a variety of caretakers, this pattern proved adaptive for these contexts.

Principally, the variance of attachment strategies suggests that attachment patterns evolved due to the necessity of children to adapt to various circumstances. Therefore, different attachment strategies must be regarded as adaptations themselves, not coercively maladaptations (Belsky, 1999, 2006). Sociobiologists provide support for this view and argue that the steady frequency of the so-called insecure patterns found in studies using the SSP speaks against a genetically preprogrammed biological normativity of the secure pattern (1998). Consequently, attachment patterns must be evaluated against the context within which they develop. A possible outcome of this approach may be that strategies that do not resemble the secure attachment pattern still represent an 'optimal' strategy – when situated in their context.

Outlook

Attachment theory is one of the most influential theories of developmental psychology to date. However, the phenomenon of attachment requires a complex analysis devoid of Eurocentric assumptions. In theory, the attachment system is designed as a system that adapts to environmental conditions and empirically, this has been demonstrated on an individual

level in many cases. Taken to its logical end, attachment theory turns into a cultural theory that integrates cultural values and norms and is therefore 'context informed.' Empirically, 'serious' cultural attachment research would significantly increase our understanding of the cultural determinants and variations of attachment and would allow an interpretation of both cultural and individual differences.

From another angle, practitioners, e.g., therapists or social workers, also call for a context-informed attachment theory. A huge number of intervention and prevention programs are based on attachment theory's assumptions of normal and healthy development, but practitioners working with children and families from non-Western societies oftentimes realize a gap between the needs of their clients and the treatments they can offer. Theory and practice rely on different languages, practices, and ideas. Whereas theoretical knowledge is mainly derived from the so-called weird – *w*hite, *e*ducated, *i*ndustrialized, *r*ich, and *d*emocratic – populations (Henrich et al., 2010), research in the non-Western 'majority world' is still widely lacking; with the consequence that programs often do not fit for their target populations.

Researchers become more and more aware of these problems and work on closing the gap: Recently, scientists from various disciplines such as cultural and cross-cultural psychology, cultural anthropolgy, ethnology, linguistics, and evolutionary science started to bring together their multicultural expertise to show that attachment looks differently and has different developmental trajectories across contexts, highlighting the need and possibility to incorporate contextual variation systematically into attachment theory. Two edited volumes are in press today, one titled 'Different faces of attachment: Cultural Variations on a Universal Human Need' (Cambridge University Press) by Hiltrud Otto and Heidi Keller, the other one titled: 'Attachment Reconsidered: Cultural Perspectives on a Western Theory' (Palgrave Macmillan) by Naomi Quinn and Jeanette Mageo. It seems that the future will bring new conceptual developments to the seminal groundwork that John Bowbly and Mary Ainsworth already laid with their formulation of attachment theory.

Attempted Utopias and Intentional Communities

Adrienne Redd, Schools for Sustainability, Philadelphia, PA, USA
Tsvi Bisk, Center for Strategic Futurist Thinking, Ziv Group, Ltd., Kfar Saba, Israel

Abstract

The authors define 'attempted utopias' as historical communities founded on systematic principles intended to promote optimal cooperation and fulfillment for their inhabitants. Real-life utopian communities have been predominantly Protestant-based reform movements in the United States from the eighteenth century through the present, though there are notable exceptions, such as ecological communities, and wholesale social reorganization as in the Chinese and Russian Revolutions. Other important themes in utopian experiments entail rethinking the family, sharing of work, and management of environmental resources, such as soil, water, energy, and organic residues.

Attempted Utopias and Intentional Communities

Utopia (pronounced/uːˈtoʊpiə/) can be defined as a proposal for harmonious society governed by a reinvented politicolegal system. No known society has achieved this ideal state, but scores of innovative communities have been organized around central principles meant to systematically address members' needs and ameliorate social problems. Because of the inherent impossibility of actualizing a perfect society, 'intentional community' rather than 'utopia' is a more precise term for such projects undertaken in the real world.

An intentional community is a residential group that defines and consents to a philosophy of how to live and work with a high degree of mutual benefit derived from cooperation, camaraderie, and shared values and responsibilities. An intentional community can be as small as an extended family or as large as a nation-state. The word 'intentional' reflects the attempt to consciously base the community on a set of principles consensually shared by participants who enter into membership voluntarily. Some scholars, such as the author of *California's Utopian Colonies*, add the criterion that a utopian community withdraws from mainstream society (Hine, 1953). However, for the purpose of this historical survey, we will also consider revolutionary movements whose intent was to be transformative for society overall. Examples include the Russian and Iranian revolutions. In his definition of 'utopia' Hicks adds that "[U]topian[s]…seek, by their example, to convince the world of the superiority of the new social institutions they have built" (Hicks, 1987).

Christian (and Islamic) Roots of Utopian Thinking

Although there are ancient, medieval, Renaissance, Islamic, and Eastern works of imagination that describe ideal societies, utopian attempts of the eighteenth and nineteenth century predominantly have ideological roots in the Protestant Reformation. A companion article in this reference work traces literary and philosophical utopian thought from Classical writing through the late twentieth century and examines some non-Christian and non-Western works.

Utopianism as it was attempted historically is predominantly based in the apocalypticism of early medieval Christianity, the Protestant Reformation, and the American Enlightenment. "The perfectionist goals of eventually overcoming sin and achieving human perfection on earth had roots in the earliest development of Christianity, with its millennial expectations of Christ's imminent second coming. As Christianity developed into an established religion, such millennial concerns were largely relegated to an indefinite future. Similar concerns resurfaced, however, at the time of the Protestant Reformation as well as in nineteenth-century America among groups that rejected Calvinist beliefs that human beings were totally depraved and could be saved only by the intervention of a mysterious, utterly transcendent God. Methodists, for example, argued that individuals could play an active role in achieving their salvation and saw salvation as an ongoing process, not absolute…" writes Pitzer (1997), a historian of Communal Protestant utopian settlements.

Monastic Christian practice began in the third century AD and gained momentum after the fall of Rome in AD 476 (Gospel of Judas, 2006). Saint Benedict of Nursia (*c.*AD 480–*c.*543) founded the Benedictine order which established ascetic, communal living arrangements (perhaps in emulation of the endurance shown by Jesus during his 40 days in the desert). During the Middle Ages several lay religious groups such as the Beghards and Brothers and Sisters of the Free Spirit also engaged in communal life. In allowing gender integration, these communities differed from the earlier Catholic and Orthodox monasteries who demanded complete separation of the genders (and total celibacy) as a demonstration of the unearthliness of religious life.

At the end of the tenth century in Europe there were plagues, fires, and disasters. Devout, literal-minded Christians believed the events of the Book of Revelations were imminent and that the second coming would take place in the year 1000. Historians, led by Jules Michelet, have drawn a dramatic picture of the expectation of mass apocalyptic events climaxing at the end of the first millennium AD. Michelet's assessment was that eschatological fervor aroused hope in the oppressed – and terror in the oppressors and catalyzed political transformations of eleventh-century France (Landes, 2000).

About a century earlier, Abū Nasr Muhammad bin al-Farakh al-Fārābi (known to European intellectuals as Alfarabius or Avennasar) wrote *On the Perfect State*, which resonated through both the Islamic world and Medieval Europe. The work shares

 http://dx.doi.org/10.1016/B978-0-08-097086-8.32195-X

with Augustine's *City of God* the assertion that only from the sound moral life of the individual can a harmonious community flow. On such individual lives can the perfect city state be built. This reside (*sic*) within a perfect world state and all under the precepts of religious doctrine (Christian for Augustine and Islamic for al-Fārābi) (Al-Farabi, 1985). However, Islamic ideology never separated the sacred from the mundane as did the accountants of the earliest Catholic universities. This Islamic expectation of the unity of the individual in the community, within the polity, within a world system under God may explain why Islamic culture did not nurture the settlements and experiments that the Christian world did.

The Reformation and the American Enlightenment

Though there are earlier Anabaptist breaks from the Catholic Church, most scholars place the origins of the Protestant Reformation in the teachings of Martin Luther (1483–1546) (and John Calvin (1509–64)). The ideas of these two leaders, one German, one Swiss, fundamentally changed western European societal attitudes about relationship between religion and work. Luther's beliefs rejected the medieval conception of labor within a hierarchy of professions. Rather, Luther asserted that all forms of work offered equal spiritual dignity. This influence can be seen in the way that almost New World Protestant utopian attempts are organized around how work is honored and evenly distributed among the hands that might plow fields, mend clothes, and prepare food, etc. This dismantling of the hierarchical nature of work in the Medieval world was continued in twentieth-century intentional communities in which previously gendered work, such as caring for children, became more evenly distributed.

Access to books (particularly the Bible) in Europe after the inception of the movable type printing press in the mid-fifteenth century made it possible for people to interpret sacred texts for themselves. Starting in the late fifteenth and early sixteenth centuries, Pietist and Protestant movements condemned the corruption of the Catholic Church, which had strayed away from practice stipulated in those sacred texts. Max Weber interpreted Protestant urgency for social reform as follows – that the Protestant elimination of monasteries turned the entire world into one immense monastery in which, as Sebastian Franck put it, "every Christian had to be a monk all of his life" (Weber, 1958).

One of the divergences from Catholic practice salient to the utopian impulse was the rejection of the practice of infant baptism, through which members into the religious community were inculcated within the first few days of being born. Christians who held that prospective members of faith should *choose* to join the religious community were called Anabaptists; they did not initiate members until young adulthood. Even twenty-first-century children reared in Amish communities are not technically 'Amish' until they join voluntarily and are baptized between the ages of 16 and 25.

The geographical location and timing of utopias and utopian communities suggest that they spring from the struggle between Catholicism and Protestant Christianity. This struggle dates to the break from the Catholic Church by Henry VIII.

In 1516, the first version of Thomas More's *Utopia* was published, criticized through fantasy the organization of wealth and the exploitation of the poor in late Medieval Europe. The year after *Utopia* was printed, Martin Luther set in motion events which led to the Protestant Reformation – in which Europe divided permanently on religion. Luther broke away from the Catholic Church altogether.

The English King Henry VIII was a personal friend of More, and made him lord chancellor of England (the highest legal office in the country). As chancellor, More was responsible for burning Protestants. More, like other humanists, had criticized many aspects of the church, but he was unwilling to split from it; he thought that if religious unity amongst Christians was undermined, the result would be disaster for Europe and civilization. So More acted ferociously on his belief that heretics had to be eradicated.

When Henry VIII broke with the Catholic Church, More resigned his job, and in 1535 was beheaded for his opposition to the king's divorce from Catherine of Aragon and marriage to Anne Boleyn. More died for his Catholic faith (and was made a saint centuries later); he himself was intolerant of non-Catholics. Yet in More's seminal book the citizens practice religious toleration, suicide, euthanasia, and divorce, all condemned by the Catholic Church. Not even More's life and writing yield a definitive answer to how a utopia should be organized, but they do point to the issues that nearly every utopian attempt must confront.

The New World and Pietist Intentional Communities

As humanistic philosophy spread throughout Europe during the Renaissance, another factor was added to the utopian impulse: the European encounter with the Americas. The 'New World' offered the potential for the actual establishment of communities that were previously only imagined, such as the travelogue of Thomas More's *Utopia*. British and other colonies in North America offered affordable land and religious freedom, as in Pennsylvania, founded on William Penn's promise of toleration of all faiths. In fictional and philosophical proposals meant to improve upon existing social arrangements it has been necessary to make a fresh start – to leave behind or wipe clean the slate of previous civilization. This is why so many literary and attempted utopias have been set on islands or in remote rural areas.

Granted a huge tract of land by King Charles II (in payment for a debt owed to Penn's father), William Penn became a real estate promoter, city planner, and governor when he founded his 'Holy Experiment' and sanctuary for Quakers in the prerevolutionary province of Pennsylvania in 1682. It became a haven of toleration for pietist, communitarian, and free-thinking groups who were leaving an intolerant Old World for the open religious climate of the British colony.

After freedom of religion was encoded into the U.S. Constitution, the Enlightenment idea of progress continued to blend with reformism to create an American incubator of social experiments from Maine to Kentucky and New York to California. These factors generated an energy and moral certainty that has characterized the American public sphere ever since.

The notion that individuals and nations can, by their own actions, make a better life for themselves rather than wait passively for the latter day constituted the very spirit of the Enlightenment and modernity's emphasis on humanism and rationality. Attracted by the promise of social inclusion within Penn's experiment (Pennsylvania) and arable land in the Mid-Atlantic, religious utopian societies from Europe streamed to the United States from the eighteenth century on; these included the *Society of the Woman in the Wilderness* (led by Johannes Kelpius), the 'Solitaries' who established the Ephrata Cloister, and the Harmony Society, among many others.

After freedom of religion was encoded in the U.S. Constitution, the Enlightenment idea of progress continued to blend with reformism to create an American incubator of social experiments from Maine to Kentucky and New York to New Mexico. These factors generated an energy and moral certainty that has characterized the American public sphere ever since. The Progressive movement, with both high ideals and petty prejudices, was the definitive example of this social trajectory.

The notion that individuals and nations can, by their own actions, make a better life for themselves rather than wait passively for the world to come was the very spirit of the Enlightenment and modernity's emphasis on humanism and rationality (Bury, 1920/1932/1955). Even before dissatisfied Lutherans in Germany turned to pietism, the movement, founded by Jan Hus, started what is now the Czech Republic in the 1450s. Hus organized his pietist groups as the Moravian Brethren. The term 'Moravian' comes from the original exiles who came to Saxony in 1722 from the Eastern European region of Moravia to escape persecution, but the Moravian Church actually began in 1457 in Kunvald, Bohemia, an autonomous kingdom within the Holy Roman Empire. Over the centuries they passed on their own practices and also absorbed influences from Anabaptists, then Baptists and Methodists. The Moravian Church (or Unitas Fratrum, meaning 'Unity of the Brethren') is one of the early Christian groups that settled in Pennsylvania. Moravians emphasize Christian unity, personal piety, missions, and music as intrinsic to worship. Their settlements in Bethlehem, Pennsylvania (in 1741) and elsewhere in the New World were communes, in which men and women lived communally and separately until marriage, and property and work were shared. They were among the first industrialists in what would become the United States, and harnessed water power to run their tanneries, grist mills, and oil mills. Over time, the collectivist nature of Moravian settlements changed; however, the church still exerts social and political influence in Moravian communities from Bethlehem, Pennsylvania to Bethel, Alaska.

Johannes Kelpius (1667–1708) was a German pietist, mystic, musician, and writer, interested in the occult, botany, and astronomy, who came to believe with his followers in the pantheist 'Society of the Woman in the Wilderness' that the end of the world would occur in 1694. Kelpius felt that the seventeenth-century Province of Pennsylvania, given its reputation for religious toleration at the edge of a barely settled wilderness, was the best place to be. Philadelphia had been founded in 1682, but the city and the Province of Pennsylvania had quickly become a tolerant haven and refuge for many pietist, communitarian, or free-thinking groups who were leaving an intolerant Old World for the congenial religious climate of the British colony. Kelpius and his followers crossed the Atlantic and lived in the valley of the Wissahickon Creek in Philadelphia from 1694 until his death. It is reported that they lived communally, though they also spent time in solitary meditation in caves and small cells scattered about their common living area. Though no sign or revelation occurred, the faithful, known as the Hermits or Mystics of the Wissahickon, continued to live in celibacy, searching the stars and hoping for the end of earthly time.

The Harmony Society was a Christian theosophy and pietist group founded in Germany by George Rapp in 1785. Its adherents were known as Harmonists, Harmonites, or Rappites. Due to religious persecution by the Lutheran Church and the government in Württemberg, the society moved to the United States in 1803, settled in Pennsylvania, and on 15 February 1805, about 400 followers formally organized the Harmony Society, placing all their goods in common. The society established three communes: Harmony, PA, Harmony, Indiana (the predecessor to Robert Owen's New Harmony), and one at Economy, PA, which was a pioneer in the American silk industry, and became the American silk center in the 1830s and 1840s. The group lasted until 1905, making it one of the longest-running financially successful communes in American history.

Religious Revivalism on American Soil

Historian Sydney Ahlstrom describes a 'great international Protestant upheaval' of the 1730s and 1740s that emphasized personal experience rather than authority and led people to be more passionately involved in their religion (Ahlstrom, 1972). Thomas Kidd goes on to make the extended argument that the First Great Awakening of the early eighteenth century intermingled the passions for salvations with yearnings for political freedom as well, leading the American colonies into a revolution and complete severance from England (Kidd, 2007).

A major figure in the Second Great Awakening in the U.S., Charles Grandison Finney preached in 1835 On Revivals of Religion (1835) that individuals *and* societies could be 'saved' by conscious decisions either by accepting Jesus, in the case of individuals, or by living according to the laws of God and the teachings of Jesus, in the case of societies. Reform-minded, Finney also advocated equality for women and African-Americans and became president of Oberlin College, the first American college to admit female and black students. Since it is hard for the individual to be virtuous in a sinful society, overarching social reform was deemed necessary and this generated a wide and creative variety of projects.

The Shakers and Other Communal Utopians

The longest lived (1747–present) and among the best-known Protestant intentional communities were the Shakers (self-identified as *The United Society of Believers in Christ's Second Appearing*), who originated in England in the eighteenth century but emigrated to America to seek a more complete manifestation of their vision. The members looked to women

for leadership. Jane Wardley, an articulate preacher, urged her followers to repent because the return of the true church was imminent. Ann Lee joined the group in 1758 and soon assumed leadership. The death of her four children in infancy traumatized 'Mother Ann,' as her followers later called her. She claimed numerous revelations regarding the fall of Adam and Eve and directed her followers to abstain from all sexual intercourse. Shakers practiced celibacy and communal ownership of goods, along with a strict separation, but total equality of the genders in work and leadership. They also adopted and educated children left in their care.

Manufacturing was a primary reason for the early success of the Shakers, but automated production and new laws concerning the adoption of orphans contributed to their decline. Membership dwindled in the early twentieth century. Many Shaker settlements have now been converted into museums; as of this writing three Shakers abide on the last working farm in Sabbathday, Maine.

The Zoarites were another communal society that came to Philadelphia from Germany in 1817. Their religious views were inspired by Jakob Böhme, a mystic who rejected salvation by faith alone and believed that the travails of man enabled God to achieve self-awareness – i.e. that human behavior during corporeal life affects the very being of God. This is a proactive belief system amenable to the essence of social reform. Sympathetic Quakers funded their migration to Ohio, where they established a communistic settlement. The death of their charismatic leader led to a decline in the cohesion of the village. By 1898, the village voted to disband the communal society and the property was divided among the remaining residents.

Christian intentional communities and attempted utopias were once so prevalent in the nineteenth century that the western and central region of upstate New York was referred to as the 'Burned-Over District,' meaning that the wildfire of radical religious experimentation and reform had so thoroughly consumed the region that there was no fuel (potential new members for the various movements) left to be ignited. Religious movements in the Burned-Over District included the Mormons, the Shakers, and the Oneida Society. Also emerging from the reformist fervor of New York in the late nineteenth century was Elizabeth Cady Stanton, who organized the Seneca Falls Convention and established the women's suffrage movement in the United States.

Extant Anabaptist Utopian Communities

The extant Amish, Hutterites, and Mennonites are direct descendants of the Anabaptist movement. The Hutterites are a communal branch of Anabaptists who, like the Amish and Mennonites, trace their roots to the Radical Reformation of the sixteenth century. Since the death of their namesake Jakob Hutter in 1536, the collectivism, pacifism, and piety have resulted in hundreds of years of odyssey through many countries. Nearly extinct by the eighteenth century, the Hutterites found a new home in North America. Their population grew from 400 to around 50 000. Like the Amish in the farmlands of Pennsylvania, Ohio, and Texas, Hutterites live in rural regions of Western Canada and the upper Great Plains of the U.S. They live on community farms or *bruderhöfe*, each one of which is home to about 15 families.

The Bruderhöfe Communities ('place of brothers' in German) are Christian religious communities with branches in New York, Florida, West Virginia, and Pennsylvania in the U.S., the United Kingdom, Germany, Paraguay, and Australia. They were previously called The Society of Brothers and were loosely affiliated with the Hutterian Brethren. The group is also known as Church Communities International. Most contemporary communities have a nursery, kindergarten, school, communal kitchen, laundry, various workshops, and offices. Bruderhöfe life is built around the family, though there are also single community members. Children are an important part of each community and participate in most communal gatherings. Disabled and elderly members are cared for within the community and participate in daily life and work as much as they are able. Like the Hutterites, the Bruderhöfe members do not hold private property individually, but rather share everything in common. No Bruderhöfe member receives a salary or has a bank account. Income from all businesses is pooled and used for the care for all members, and for various communal outreach efforts.

The Hopedale Community was a religious commune founded in Worcester County, Massachusetts in 1842. Their principles were temperance, abolitionism, women's rights, spiritualism, and education. When the commune went bankrupt in 1856 it became a textile factory, a resonance of the Oneidans who continued making utensils long after their social experiment dissipated.

Utopians in the American West

Subsequent to the northeastern states welcoming intentional communities, utopian settlers moved west and south, in search of independence and open space in which to conduct their social experiments. Fountain Grove was a utopian religious cooperative in California founded in 1875 by Thomas Harris who established a movement called the Brotherhood of the New Life. He had previously founded two similar communities in New York State. The movement's most prominent member was Laurence Oliphant who was sent to Palestine by Harris to explore the possibility of setting up a similar utopian community. Oliphant tried to obtain a lease for the Galilee region from the Turkish Sultan in order to resettle the Jews and bring about the end of days. This took place a full decade before Theodore Herzl wrote *The Jewish State* (1896).

The Church of the Latter Day Saints, also known as the Mormon Church, was founded in 1830 by Joseph Smith, who claimed that God had led him to a new set of scriptures called the Book of Mormon about the presence of Jesus in North America. It became another collectivist project which in retrospect is arguably utopian in its principles. Like other social innovators who have advocated for a different expression of human sexuality, Smith espoused polygamy as part of his utopian society. Smith and his followers were persecuted in Ohio and the Midwest. In 1844, a mob murdered Smith and his brother Hyrum in Illinois. Smith's follower, Brigham Young, led the followers of Mormonism to what is now Utah.

Orderville, Utah was established at the direction of Latter-day Saint (Mormon) leader Brigham Young in 1875 and followed a voluntary form of communalism defined by Joseph Smith. The town was settled primarily by destitute refugees from failed settlements on the Muddy River in Nevada. The extreme poverty of these settlers may have contributed to their devotion to the principles of the United Order.

Meaning 'House of God' in Hebrew, Bethel or Beth el or Beth-El, Missouri was a Bible-based communist utopian colony established in 1844 by William Keil. He believed that the Book of Acts required that Christians hold all property and means of production in common. He founded another religious commune in 1856 in Aurora, Oregon. He was encouraged to form his communal movement by former members of the Harmony Society. Bishop Hill Colony in Illinois was a utopian communal religious community. It was founded in 1846 by Swedish pietist Eric Janson who believed the commune would become the 'New Jerusalem' and spread reform around the world.

Jewish Intentional Communities

In 1825 Mordechai Noah, an American Jewish playwright, attempted to establish a Jewish refuge on Grand Island in the Niagara River. It was to be called *Ararat* after the resting place of Noah's Ark. Noah purchased land on the island and laid a cornerstone which read 'Ararat, a City of Refuge for the Jews,' but Jews did not settle in the City of Refuge, so the project began and ended with the ceremonial laying of that cornerstone.

In 1891, 3 years before the Dreyfus Affair and 6 years before the First Zionist Congress, the German Jewish philanthropist Baron Maurice de Hirsch created the Jewish Colonization Association (JCA). The goal of the JCA was to encourage mass Jewish emigration from Russia and Eastern Europe in order to settle them in agricultural colonies on lands purchased by the Association. The peak of JCA activity in Argentina was in 1930 with over 20 000 Jews on approximately 1 500 000 acres of land (including Jewish *Gauchos*). But town life eventually outshone the romance of the soil and by 2012 only a few dozen elderly Jews were left.

The JCA attempted something similar in Brazil in 1904 with Jews from Bessarabia (modern-day Moldova). This colony failed and was liquidated in 1928. Another colony was founded in 1909 but was abandoned even before the First World War (WWI). The JCA resettled it but this experiment finally ended in 1965. Another failed attempt was in the 1930s with German Jewish refugees.

The JCA was active in the United States and Canada and in cooperation with other groups had established 78 Jewish farms by WWI in New York, New Jersey, Pennsylvania, and Connecticut – the most famous being Woodbine, New Jersey. By the time of the Second World War (WWII), JCA activity in the United States had all but ceased. In Canada 40 Jewish farms had been established by 1930, though nothing remains of the project.

In Israel itself, the Kibbutz is perhaps the most well-known and successful twentieth-century Jewish utopian experiment. Over 270 Kibbutzim in four major ideological categories survived, grew, and flourished for over 70 years (until their ultimate crises) and were the backbone of the establishment of modern Israel. Other Israeli utopian experiments include the Moshav (small agricultural cooperative) and the Moshav Shitufi. Unlike the Kibbutz, land is not worked in common but 'held' by separate families who live in family units (private homes) and retain their own profits. The Moshav Shitufi is a hybrid of Moshav and Kibbutz. Families live as they do in the Moshav with small family-managed plots of land while certain sectors of agriculture are operated collectively as in the Kibbutz. Services and marketing are dealt with cooperatively in both these social structures; by the twenty-first century, economic downturns have all but destroyed the cooperative aspects of these experimental settlements.

Organizing Principles of Intentional Communities

Although most intentional communities have been religious (and most of those Anabaptist Protestant Christian projects), monotheistic faith is not the only organizing principle upon which utopian experiments have been built. Ownership or property, vegetarianism, ecology, and human sexuality (or celibacy) have been central principles in utopian attempts.

While some groups, such as the solitaries of Ephrata and the Shakers, chose celibacy and asceticism as a path to fulfillment, the Oneidans chose what they called 'complex marriage.' Founded by John Humphrey Noyes, the settlers in Oneida in upstate New York rejected monogamy. The reasoning behind this was that sexual possessiveness leads to overall lack of concern for the larger community. Members were encouraged to engage in free (heterosexual) copulation throughout the community; postmenopausal women were encouraged to teach young men about the joys of sex (particularly because these couplings were less likely to result in pregnancy) and the devout were encouraged to consort with the nondevout in hopes of encouraging greater religiosity.

Decisions about procreation were handled by committee, though unsanctioned children were provided for just as if they had been planned in accordance with the rules. Birth mothers were only responsible for the care of their offspring for the first few years of life; the community as a whole cared for and disciplined older offspring. Now known for its manufacture of Oneida silverware, the Oneida community lasted from 1848 to 1881, making it among the longest-running communes in American history.

The *Amana* Colonies in Iowa constitute another example of a long-running commune. Started by radical German pietists, they lasted from 1855 to 1932. Like the Moravians and Shakers, they embraced manufacturing. The Amana Corporation, manufacturer of refrigerators and household appliances, was originally started by the group.

Communal Societies

Two dominant themes in intentional communities are collectivism and agrarian life. Considering the roots of utopianism in the Protestant Reformation of the sixteenth and seventeenth century, the humanism and empowerment of

the Renaissance, and the rationality of the Enlightenment, it is necessary to consider the impact of these ideas on social upheaval of the Industrial Revolution. Starting since the 1830s in England and continuing for a century in Europe and the U.S., workers flocked to cities to work in factories and struggled visibly as capitalism and the profit motive became organizing principles of both societies. The reform movements of the nineteenth century came to emphasize distributing resources such as housing, medical care, food, and education to struggling workers and the urban underclass. However, some utopians took it upon themselves to start new communities, usually away from the squalor and turmoil of the cities, and to organize those societies around equitable distribution of goods and work.

Connected to the urge to distribute resources fairly is the question of inherent human selfishness and how reshape in the culture of the settlement so that the needs of the group precede individual desires and urges. During the nineteenth century and through the twentieth century, economic utopias sprang up around the United States in reaction to various political conservative movements. They were communal and egalitarian, sharing work and resources.

American secular utopian communities took inspiration from ideas and philosophies originating with Protestant Christian groups, but evolved their philosophy to moral-spiritual, rather than religious doctrine. Transcendentalism began as a term developed by the German philosopher Immanuel Kant (1724–1804) embodying those aspects of man's nature transcending, or independent of, experience. Taking root in America, Transcendentalism created a cultural renaissance in New England during 1830–45 and manifested its chief American expression in Ralph Waldo Emerson's doctrine of self-reliance.

Some Transcendentalists decided to put their theories about 'plain living' into practice. One experiment in communal living was established at West Roxbury, Massachusetts, on some 200 acres of land from 1841 to 1847. The Brook Farm Institute of Agriculture and Education became better known than many other communal experiments due to its distinguished founder and inhabitants. The community wasn't unique for its time; more than 80 utopian communities were launched in the 1840s alone – but it was notable as the first purely secular one. The Brook Farm Institute was organized and directed by George Ripley, a former Unitarian minister and later literary critic for the *New York Tribune*. Others connected with the project were Charles A. Dana and Nathaniel Hawthorne (both shareholders), Ralph Waldo Emerson, Margaret Fuller, William Henry Channing, John S. Dwight, and Sophia Dana Ripley, a woman of wide culture and academic experience. Brook Farm attracted not only intellectuals, but also carpenters, farmers, shoemakers, and printers. The community provided to all members, their children and family dependents, housing, fuel, wages, clothing, and food. There was daycare, a primary school, and a college, preparatory course covering 6 years.

A disastrous fire in 1846 demolished the newly financed Phalanstrey building. In combination with further financial troubles, including Hawthorne's suit against Ripley and Dana to recover his investment in the project, brought about the end of the Brook Farm community the following year. Nathaniel Hawthorne later satirized in his novel, *The Blithedale Romance* (1852).

In 1842 the Northampton (Massachusetts) Association of Education and Industry established another secular commune based on racial, gender, religious, and class equality. They wanted to replace competition with cooperation and were especially dedicated to the abolition of slavery. Sojourner Truth was a member and Frederick Douglass was a visiting lecturer.

The *Skaneateles Community* was established in 1843 by the *Society for Universal Inquiry and Reform* in upstate New York. Several similar communities were established by the society before the Civil War. It survived for 3 years. Its leaders were abolitionists. Members shared living quarters and worked in agriculture and light industry. It was economically successful but broke up because of internal dissent.

The *Icarians* were a utopian movement founded by French philosopher Étienne Cabet. He advocated workers' cooperatives instead of capitalist factories. This appealed to the artisan classes whose living was being endangered by large factories. He had been influenced by Robert Owen and, in turn, influenced Marx and Engels. His social philosophy stemmed from primitive Christianity and was detailed in his book *The Real Christianity according to Jesus Christ*. At its peak the movement had 400 000 adherents in France but still made no impact on actually reforming French society. Consequently he moved with some of his followers to the United States in 1848 where he established several egalitarian communes in Texas, Illinois, and Iowa.

Fruitlands was a utopian agricultural commune founded in 1843 by Bronson Alcott in Concord Massachusetts based on transcendentalist principles. Members were vegan vegetarians, drank only water, bathed in cold water, and used no artificial light. Property was held communally, and no animal labor was used. Celibacy was celebrated as an ideal. Although it was egalitarian in principle, Alcott's wife and the other women did most of the work and the stress of deprivation because of its extreme principles contributed to its collapse after only 7 months.

The anarchist village *Modern Times* was a community of 150 founded on Long Island in 1851. It was based on barter and existed until the Civil War when patriotism trumped social idealism and many members enlisted in the Union army. In 1864 it transformed into the prosperous suburb of Brentwood.

Some utopian writings originated in Europe, but were attempted in North America. Another influence behind Brook Farm was the writing of François Marie Charles Fourier. Fourier believed that society should be organized into small cooperative groups, and that people should largely be assigned productive work that they enjoyed, reorganization that would greatly increase society's productivity (Fourier, 1967). He proposed to eradicate poverty by providing adequate wages and guaranteeing a minimum standard of living for those not able to work. In this he anticipated the modern market-based welfare state. As many as 29 communities were founded in the United States based on Fourier's views; they included Utopia, Ohio; La Reunion, Texas; and the North American Phalanx in Red Bank, New Jersey.

Fourier envisioned cooperative communities he called 'phalanxes' living in structures called Phalanstères or 'grand hotels' (not unlike the Unité d'Habitation architectural

experiment of Le Corbusier). These buildings were four-level apartment complexes in which the richest had the uppermost apartments and the poorest resided on the ground-floor residence. Wealth was determined by one's job; jobs were assigned based on the interests and desires of the individual. There were incentives: jobs people might not enjoy doing would receive higher pay. Fourier considered trade, which he associated with Jews, to be the 'source of all evil' and advocated that Jews be forced to perform farm work in the Phalanstères.

Fourier's vision of cooperative communal subunits and a greater social safety net for workers also influenced the Paris Commune of 1871. While it only lasted 40 days and was fraught with instability, it stemmed from the communal utopian impulse and is regarded as the first socialist worker uprising. The workers of Paris, joined by mutinous National Guardsmen, seized the city and set about reorganizing society in their own interests based on workers' councils. They could not hold out, however, when more troops retook the city and massacred 30 000 workers.

A handful of communal, agrarian settlements of the nineteenth century were founded on European soil. Matti Kurikka was a Finnish utopian socialist and theosophist who helped establish *Sointula*, a utopian island colony of Finnish immigrants on Malcolm Island, British Columbia Canada based on cooperative principles in 1901. The utopian colony was dissolved in 1905.

New Lanark is a village on the River Clyde, approximately a mile and a half from Lanark, in South Lanarkshire, and some 25 miles southeast of Glasgow, Scotland. It was founded in 1786 by David Dale, who built cotton mills and housing for the mill workers. Dale built the mills there in a brief partnership with the English inventor and entrepreneur Richard Arkwright to take advantage of the water power provided by the only waterfalls on the River Clyde. Under the ownership of a partnership that included Dale's son-in-law, Robert Owen, a Welsh philanthropist and social reformer, New Lanark became a successful business and an epitome of utopian socialism as well as an early example of a planned settlement and so an important milestone in the historical development of urban planning.

Robert Owen was a social reformer and wealthy industrialist who made his fortune from textile mills in New Lanark, Scotland. Owen and his 22-year-old son, William, sailed to the United States in 1824 to purchase a site to implement his vision for 'a New Moral World' of happiness, enlightenment, and prosperity through education, science, technology, and communal living. Owen's utopian community would create a 'superior social, intellectual and physical environment' based on his ideals of social reform. Owen and his followers and successors were known as Owenites. Owenism aimed for radical reform of society and is considered a forerunner of the cooperative.

New Harmony became known as a center for advances in education and scientific research. New Harmony's residents established the first free library, a civic drama club, and a public school system open to men and women. Its prominent citizens included Owen's sons, Indiana congressman and social reformer Robert Dale Owen, who sponsored legislation to create the Smithsonian Institution; David Dale Owen, a noted state and federal geologist; William Owen; and Richard Owen, state geologist, Indiana University professor, and first president of Purdue University. The town served as the second headquarters of the U.S. Geological Survey and numerous scientists and educators contributed to New Harmony's intellectual community, including William Maclure, Marie Louise Duclos Fretageot, Thomas Say, Charles-Alexandre Lesueur, and Joseph Neef, Frances Wright.

Literary Influences on Utopian Attempts

One of the most influential fictional visions of a collective society was Edward Bellamy's *Looking Backward: 2000–1887* (1888), which was translated into dozens of languages and influenced popular readers, intellectuals, and reform movements. In the novel, the Eastern United States has peacefully transitioned to a society where there is no money and each citizen is productive to the best of his or her ability and takes what he or she needs from communal dining halls and well-stocked shops. *Looking Backward* had a profound impact on the minds of reformers who were well aware of the upheaval, deprivation, and widening of the gap between rich and poor caused by the Industrial Revolution.

Topolobampo was the site of a utopian colony from 1884 to 1894 in Mexico. It was the socialist utopian vision of Albert K. Owen and was settled by farmers from New England. The members believed in 'Collective ownership and management for public utilities and conveniences and the community being responsible for the health, usefulness, individuality and security of each.' The colony influenced the garden city concepts of Ebenezer Howard who had himself been influenced by Bellamy's utopian novel of 1888, as well as Henry George's economic article, *Progress and Poverty*, an example of the indirect influence of utopian literature on society.

Revolution as Utopianism

While European and American workers struggled with the upheavals of the Industrial Revolution, Russia reeled with the aftermath of the liberation of the serfs and problems with distribution of land. The Russian Revolution of 1905 was a wave of worker strikes, peasant unrest, and military mutinies that spread through the Czarist Russia. It catalyzed the establishment of a limited constitutional monarchy, the *Gosudarstvennaya Duma* (State Assembly), a multiparty system, and the Russian Constitution of 1906. Although he saw violent revolution as an illegitimate source of reform, Max Weber considered this a great opportunity for renewal of Russia and an opportunity for sweeping solutions to the major economic and social problems of turn-of-the-century Russia, namely more equitable distribution of land to the peasants and sharing of political power (Weber, 1995). He specifically refers to the potential for revolution to be utopian; interestingly, the German word 'Utopische' has the same connotation as it does in English – that of a proposal being sweeping, idealistic, and overambitious.

Mao Zedong and Mohandas Gandhi were born in the East but their thinking was based in the forward-thinking, scientifically based paradigm of modernity. The thrust toward

modernity differs in Asia's two leviathans but their modernity is unquestionable (Friedman and Gilley, 2005). Gandhi and Mao expressed their views in Indian and Chinese cultural trappings to popularize them, yet Gandhi's attitudes toward eliminating caste and Mao's desire for women's equality were more western than eastern.

It was not the idealist dimension of the peasant revolutions that caused them to sour, however. It was the willingness to crush the individual in pursuit of the total reorganization of society, and the way that Soviet totalitarianism played out in the public consciousness. The view of peasant revolutions as utopian was quickly quashed as citizens of such states revealed their brutal dimension in dystopian fiction that barely exaggerated the oppression of the Soviet Union, such as Yevgeni Zamyatin's *We* (1924), Ayn Rand's *Anthem* (1938), and scathing satires of Soviet Russia, such as Alexander Zinoviev's *Yawning Heights* (1976). As dissidents fled persecution, even children's fiction incorporated glimpses of what a society becomes when it sacrifices individuality for stability and conformity. The scene in the city of Camazotz of a boy bouncing a ball in perfect rhythm in a reeducation chamber in Madeleine L'Engle's *A Wrinkle in Time* (1962) chillingly captures the horror of Soviet Gulags and reeducation camps, as well as American anxieties in the U.S. at the time the book was written (Halberstam, 1994).

Technology and Futurism

Although the Amish and old order Mennonites reject technology beyond an arbitrary point as distractions from their spiritual pursuits, some groups, notably the Shakers, Oneidans, and Amana Colonies, embraced and even innovated new technologies.

Eventually founding two dozen communities in New York, Connecticut, Massachusetts, New Hampshire, Maine, Kentucky, Ohio, Indiana, Florida and attracting over 20 000 converts, the Shakers enjoyed their heyday in the nineteenth century, creating a number of technological advances including commercially packaged seeds and opium, the circular saw, the flat broom, the pencil-end eraser, as well as highly functional and starkly elegant furniture and architecture.

While the majority of utopian communities have been faith-based, there have also been rational and systematic social experiments. In a scientific approach to finding utopia, the Global Scenario Group, an international group of scientists founded by Paul Raskin, used scenario analysis and backcasting to map out a path to an environmentally sustainable and socially equitable future. Its findings suggest that a combination of global grassroots momentum and political will is necessary to steer political, economic, and corporate entities toward this new sustainability paradigm. Fictional visions of the misuse of technology, as in the surveillance screens in Orwell's *1984*, and industrialized human reproduction in Huxley's *Brave New World* have also contributed to dystopian fears.

Architectural Experiments and Ecovillages

Epiphanies about environmental degradation and the finiteness of the planet were of the cultural forces that stimulated some utopian impulses during the 1960s and the 1970s. Arcosanti, an experimental town on 25 acres in central Arizona, is an example of a secular, environmentally oriented intentional society that has integrated the use of specific technologies in order to make life in the desert workable. Construction began on the project in 1970 and most construction was complete by 1989. Though neither as prosperous nor as populous as Matrimandir (discussed below), Arcosanti has about 150 permanent residents. Founded by Italian-American architect and artisan Paolo Soleri (who retired as president and CEO at the age of 92 in 2011).

Matrimandir of auroville

The purpose of the Arcosanti was to demonstrate that architecture and ecology could be combined into 'archeology' and lessen the destructive impact of human habitation on the planet. The principal economic activity of the community (in addition to growing food) is the casting of bronze sculptural bells. As in a kibbutz, residents live in family apartments, but shared cooking and other work, including the casting of bells, which was the principal economic activity of the complex. One of the challenges of the community has been how members can make a living through a combination of mandatory work at Arcosanti and still have sufficient time to be employed outside the settlement.

One of the most enduring and globally regarded ecovillages is Auroville, a city of 2300 people on 60 acres of denuded land (which had only a solitary banyan tree when the project started) on the east coast of India in Tamil Nadu. The community grew out of the work of an advocate for Indian independence, Sri Aurobindo, who founded an ashram near

Pondicherry on the principle of what he called 'integral yoga.' Aurobindo cofounder, a Frenchwoman named Mirra Alfassa, who came to be known as 'the Mother' outlined a charter for the community, emphasizing cooperation and the idea that material manifestations of harmony with nature (such as food and energy production and water and waste management) are crucial to healthy spirituality.

Endorsed by UNESCO and comprising people from over 40 countries and built around a huge golden dome, called Matrimandir, the city has capacity for 50 000 people. It has continued to grow in population each year and asserts the goal of embodying a global paradigm shift toward sustainability.

Another ecologically oriented architectural community is the Findhorn Ecovillage located near Moray, Scotland. Founded in 1962, the purpose of the project was to demonstrate a human settlement that was sustainable in environmental, social, and economic terms. Approximately 450 members of the 'ecovillage' live and work there, engaging in ecohouse construction; a 75 kW Vestas wind turbine and an ecological waste water treatment system were all undertaken by the Findhorn Foundation itself; other independent practitioners have been attracted to the area and have diversified the ecological and demonstration projects.

The back-to-the-land movement in the United States and elsewhere called for people living on any sizable piece of land from a city lot to ample acreage to grow food from the land on a small-scale basis for themselves or for others. The concept was popularized in the United States at the beginning of the twentieth century by activist Bolton Hall, who set up vacant-lot farming in New York City and wrote on the subject.

Communal Experiments of the 1960s and 1970s

Distributism was an attempt during the 1920s and 1930s to find a third way between capitalism and socialism. It was later used to refer to a North American social phenomenon of the 1960s and 1970s. This latter back-to-the-land movement was a migration from cities to rural areas that took place in the United States, its greatest vigor being in the late 1960s and early 1970s.

During the nineteenth century, California was home to diverse utopian political experiments. These 'old utopian communities' were built on themes ranging from communitarian, socialist and Fourierist, that being the proposal that society be organized into small self-sustaining settlements. Life in these communities entailed hard work and simple living conditions. They were frugal and isolated from the conveniences of late-nineteenth-century life. In sociological terms, most of these communities were 'total institutions' (Goffman, 1961) because they encompassed most of the life-space of their members. Few of the communities lasted more than 10 years. While most of them disbanded by 1900, there were continuing experiments with cooperative utopian communities through the twentieth century in California and other states. In the 1960s, the West Coast was again the cradle of developing small cooperative communities.

Many back-to-the-land and communal arrangements conceived in the heyday of Haight-Ashbury disintegrated; Drop City was an artists' community that formed in southern Colorado in 1965. It became known as the first rural 'hippie commune.' Inspired by the architectural ideas of Buckminster Fuller and Steve Baer, residents constructed domes and zonohedra to house themselves, using geometric panels made from the metal of automobile roofs and other inexpensive materials. In 1967 a group consisting of 10 core people won Buckminster Fuller's Dymaxion award for their constructions. The project was abandoned by the early 1970s.

Zonohedron constructed at the burning man festival

Several intentional communities from that era have endured. One is The Farm, a 1750-acre commune in Tennessee founded by Stephen Gaskin, a former English professor at San Francisco State University. Traveling from California in a caravan of 60 buses, vans, and trucks in 1971, its residents pooled their money to buy land in Lewis County, near the town of Summertown. They installed their own water system and had their own electrical crew, composting crew, farming crew, construction and demolition crew, clinic, firewood crew, alternative energy crew, motor pool, laundromat, tofu plant, bakery, school, and ambulance service. It established The Book Publishing Company, which published the works of the Gaskins and other Farm members. The Farm's midwifery school and Ina May Gaskin's seminal book *Spiritual Midwifery* are well known throughout the world for their emphasis on maternal and newborn compassion, safety and success rates.

The Twin Oaks community in Louisa County, Virginia is an ecovillage and intentional community of about 100 people living on a 450-acre farm in Louisa County, Virginia. Founded in 1967, it is one of the longest-enduring and largest secular intentional communities in North America and was Initially inspired by B.F. Skinner's novel *Walden Two*, which describes a fictional behaviorist utopia. However, behaviorist principles gave way to egalitarian principles and the community has successfully functioned according to those for more than 40 years. The community struggled during its early years because of the problems stereotypically associated with communes, such as freeloading and lack of structure, but developed a structured, but flexible, labor system that has been successful. A member of the Federation of Egalitarian Communities, its basic values are cooperation, egalitarianism, nonviolence, and sustainability.

The Failure of Utopianism

Although there are some extant intentional communities, such as the last few Shakers, Findhorn, Arcosanti, a few remaining kibbutzim, The Farm, Twin Oaks, and Auroville, many utopian initiatives eventually dissipated with the exception of the Hutterites and the Amish in North America and the remnants of the Kibbutz movement in Israel. The failure of so many well-intentioned initiatives pursued with such early energy and idealism has made the term 'utopian' a pejorative, synonymous with naive, unrealistic aspirations, and even oppressive control of the residents.

Disillusionment with Israel's Kibbutz movement played a part in discrediting utopianism. This had been the one twentieth-century utopian experiment given sanction by serious social science. But by the first decade of the twenty-first century only 20 out of 270 Kibbutzim were still flourishing in their original communal form. Others were barely surviving. The Kibbutz movement only survived into the second decade of the twenty-first century by abandoning unconditional equality. Differential income standards were adopted – people doing jobs that required greater skills and responsibility received greater compensation. Previously services had been available on demand according to the request of each member. Gradually, members were required to pay for their electricity, water, and food out of their own income. The consumption of these necessities plummeted (to the delight of environmentalists) enabling many previously failing Kibbutzim to regain financial stability. One of the sad realities of the Kibbutzim was that egalitarianism encouraged waste. People left their heat on high so they could come home to a warm apartment, fed food meant for humans to companion animals, and did not bother to repair dripping faucets (Unpublished interview).

Second- and third-generation kibbutzniks had already radically changed the internal social structure of the Kibbutz before the financial crisis and in doing so contributed to it. Those raised in communal children's houses (an experiment celebrated in scores of social science books as an alternative to the traditional family) had painful memories of their experience and refused to raise their own children in the same way. Anecdotal articles as well as substantial research and lawsuits undermined the halcyon myth of the 'children's house', revealing physical, sexual, and psychological abuse.

The subsequent necessity of expanding family dwellings resulted in great expense, which became a major contributor to subsequent financial problems. Many people sympathetic to the kibbutz ideal concluded that idealistic wishful thinking can produce adverse social structures which result in economic difficulties, social disintegration, and the loss of individual self-esteem for members of the community. This appears to have been the greatest failure of utopianism; the inability to understand the connection between economics and ideals: that no matter how lofty the ideal, if it does not rest upon a foundation of practical, efficient, rational economic behavior it is doomed to fail. The very short life spans of the intentional communities described in this article appear to support this observation. The history of Soviet and Chinese collectivization also supports this assessment.

The examples of the Soviet Union and China, the self-indulgent communes of the 1960s and dropouts of the 1970s, and the bizarre religious communes such as Jonestown and Branch Davidians have done little to improve the reputation of utopian speculations and experiments. The dismal record of China's Cultural Revolution, the Gulags of the Soviet Union, and the killing fields of the Communist Party of Cambodia during the twentieth century have made utopianism less promising. It has been estimated that governments having utopian pretensions as their foundational societal axiom killed over 50 million people in the twentieth century. Stalinism, The Great Leap Forward, The Cultural Revolution, Pol Pot, and other 'utopian' phenomena have piled up bodies in numbers inconceivable to even Genghis Khan, Attila the Hun, and Ivan the Terrible.

Totalitarian Dilemma within Utopianism

"The main reason that utopian thought went out of fashion was the link drawn between utopianism and the totalitarian regimes that blighted the twentieth century," writes Craig Smith (2005). Sargent (2010) also notes the trajectory from utopian thought to totalitarianism and Goodwin and Taylor (1892/2009) wrote, "[F]actors conspired, in the 1920s and 1930s, to alter the prevailing mood from optimism to despair: widespread economic depression, the constant threat of war, the instability of liberal democracy, the rise of Fascism. Not surprisingly dystopian rather than utopian speculation texts figured prominently in the literature of this period, the most notable examples being Zamyatin's *We* (1920), Huxley's *Brave New World* (1932) and Orwell's *Nineteen Eighty-Four* (1949). The realities of Fascism and Stalinism were taken as warnings of what a modern scientific-technological systems, established in the name of utopianism, might be like." The focus on one main social problem makes almost all utopian writing and almost all intentional societies one-dimensional and therefore potentially totalitarian. Since literary (and attempted) utopias are based on a single main ideology this intense focus can lead utopian aspiration over the line into the temptation to force all member of the society to adhere to the precepts and procedures of the supposedly ideal society. That is, if the founders of the utopian experiment have great certainty that they know best, they may be willing to exert brutal means to bring citizens in line with their vision. Total control over

communications with the outside world has been characteristic of every twentieth-century totalitarian society with utopian ambitions. Twentieth-century 'utopians' like Stalin, Mao, Pol Pot, and Kim Il-sung all made their societies social, cultural, and 'economic islands,' and in doing so, also made them dystopias.

Utopianism Promoted Reform

A utopia is a society that attempts to eliminate all social problems. By that definition, because human beings are imperfect, no human society can ever completely avoid all suffering, deprivation, friction, or selfishness among its members. All but a few attempted utopias of the nineteenth and early twentieth century failed in terms of their own standards, but they did lead the rest of society toward meaningful reforms in distribution of resources, the reconceptualization of work, greater equality for women and nonwhites, and even greater productivity through technological innovation.

One example of failure that nevertheless produced social progress can be seen in the efforts of Robert Owen. The Owenite movement established several communities according to communitarian and cooperative principles. One of the best known of these efforts, which were largely unsuccessful, was the project at New Harmony, Indiana, which started in 1825 and was abandoned by 1829. In spite of this short-lived project, Owenism is also closely associated with the development of the British trade union movement, and with the spread of the Mechanics movement, and therefore had a lasting impact on society.

Conclusion

Just as the title of Sir Thomas More's fictional travelogue combining the 'eu' the Greek word root for good (as in eulogy or euthanasia) and 'u' meaning 'not' plus 'topia' meaning place, the words 'utopia' and 'utopian' have many and contradictory connotations: ideal, visionary, oriented toward reform, quixotic, unrealistic, or even totalitarian, as in the title of the biography of one of the ideological architects of the Iranian Revolution, *An Islamic Utopian*.

The intellectual intolerance of Plato and moral intolerance of the Bible produced one particular type of utopian thinking that dominated fictional visions as well as social experiments – a categorical certainty that resulted in burning religious reformers at the stake, guillotines and gulags to purify society from dissent and difference. Until and unless utopian thinking can learn to entertain several mutually contradictory ideas at the same time it will lead to social oppression in practice and remain suspect in theory. If utopian literature is to continue to have relevance and impact on the thinking of social planners, it must resolve this quandary.

Attention-Deficit and Hyperactivity Disorders, Neural Basis of

Irene M Loe and Heidi M Feldman, Stanford University School of Medicine, Stanford, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Understanding that attention-deficit/hyperactivity disorder (ADHD) had a neural basis was first based on association of neurological conditions with behavioral manifestations of the disorder. Since those early observations, ADHD diagnosis continues to be made on the basis of clinical symptoms, although the psychological and biological mechanisms underlying the disorder have been better elucidated. Recent advances in neuroscience coupled with genetic, environmental, and psychopharmacology studies shed light on the neural basis of the disorder. Structural, functional, and connectivity imaging studies of the brain show distinct differences in ADHD. Neurotransmitter systems are also affected by the disorder and targeted in treatment.

Historical Background

Early references to children with attention-deficit/hyperactivity disorder (ADHD) symptoms made no mention of possible neural origins to the condition. A German physician, Heinrich Hoffman, wrote a children's book in 1848 in which he described two characters, 'Fidgety Phil,' who demonstrated hyperactive/impulsive symptoms and was unable to sit still, and 'Johnny Head-In-Air,' who demonstrated inattentive symptoms and, while distracted, fell into a river (Hoffman, 1848). ADHD was first described behaviorally in the medical literature as a 'defect of moral control' in children with ADHD symptoms by George Still over 100 years ago (Still, 1902).

The possibility of a neurobiological basis for the disorder came decades later in the 1920s, when children recovering from influenza encephalitis caused by a worldwide epidemic in 1917 exhibited symptoms of restlessness, inattention, impulsivity, easy arousability, and hyperactivity (Hohman, 1922; Ebaugh, 1923). In 1937, the serendipitous discovery that racemic amphetamine, Benzedrine, improved ADHD symptoms in children provided additional support for a neurobiological basis for the disorder since stimulants affect brain neurotransmitters (Bradley, 1937). Various types of brain injury have been described in association with ADHD symptoms; however, the presentation of symptoms in children without obvious brain damage led to the name 'minimal brain disorder' or 'minimal brain dysfunction.' Stimulants such as methylphenidate and amphetamines were not routinely used for ADHD until the late 1950 to 1960s. Increasing use of stimulants coincided with a switch in nomenclature in the late 1960s that focused on behavioral symptoms rather than etiology, evolving from hyperkinetic syndrome to attention-deficit disorder, and most recently, to ADHD. At that time, little was known about brain mechanisms underlying pathogenesis and treatment. Clinical description of the disorder, including diagnosis and treatment, is included in the preceding article on ADHD. ADHD diagnosis continues to be made on the basis of clinical symptoms, although the psychological and biological mechanisms underlying the disorder have been better elucidated. Recent advances in neuroscience, coupled with genetic, environmental, and psychopharmacology studies, shed light on the neural basis of the disorder through structural, functional, and connectivity imaging studies of the brain, studies of neurotransmitter systems affected by the disorder and targeted in treatment, and interactions with genes and environment.

Neuropsychological Impairments

ADHD has been characterized by a wide variety of cognitive and neuropsychological impairments that accompany the behavioral symptoms of inattention, hyperactivity, and impulsivity used in diagnosis (Nigg, 2005). Various lab-based paradigms have been developed to tap different neuropsychological skills categorized under the umbrella term of executive function or cognitive control. Executive function skills are often broken down into individual constructs such as response inhibition, working memory, cognitive flexibility, organization, and planning. In addition, attention is often subdivided into different skills such as vigilance, orienting, and selective, divided, and sustained attention. Other systems involved in motor planning, motivation and reward, and timing or temporal expectations have also been implicated in ADHD. However, the presence of such impairments varies widely among individuals with ADHD and may or may not be captured by lab-based measures or parent-, teacher-, or self-ratings of such skills (Nigg, 2005). Nonetheless, these neuropsychological skills have been linked to various brain regions, originally through associations with brain lesion or injury studies, and now through anatomic and functional imaging.

Neurobiological Basis

Structural Imaging Studies

Structural imaging studies of the brain in ADHD often focus on brain volume, surface area, or both. Investigators' early focus included frontostriatal regions based on findings from neuropsychological studies in patients with brain lesions. However, findings from several studies indicate that more widespread regions or networks are involved in ADHD. Results vary from study to study. Findings of smaller volumes have been reported in the dorsolateral prefrontal cortex, caudate, pallidum, corpus

callosum, and cerebellum in children with ADHD compared to controls (Seidman et al., 2005). Findings in the caudate have varied, with results ranging from equal, larger, or smaller caudate measurements in ADHD subjects compared to controls (Valera et al., 2007). Differences in findings across studies may be due, at least in part, to low power as many structural studies have had small sample sizes (i.e., often <20 subjects/group). In addition, the influence of medications, comorbid conditions, and gender as well as other sources of heterogeneity in the populations such as ADHD subtype, family history of ADHD, and perinatal complications often were not considered (Seidman et al., 2005). Although sex-specific behavioral differences in ADHD are well described, the current neuroimaging literature, which overall has fewer female than male participants, shows no consensus on sex-specific brain anomalies or differences (Mahone and Wodka, 2008).

A meta-analysis was performed to help resolve inconsistencies across structural imaging studies regarding which brain regions are most affected or have the largest volumetric reductions in children with ADHD (Valera et al., 2007). Pooling results from 21 high-quality studies, global reductions in multiple regions characterized children with ADHD compared to controls. The regions that were most frequently assessed and showed the largest differences included cerebellar regions, the splenium of the corpus callosum, total and right cerebral volume, and the caudate. Significant differences between several frontal regions and the cerebellum were also found, although it was advised that these results be interpreted with caution due to concerns about low power (Valera et al., 2007).

High-resolution structural MRI scans have been used to quantify cortical thickness in children with ADHD. They show significant global thinning of the cortex, which was most prominent in prefrontal and lateral temporal cortices (Shaw et al., 2006). In addition, the ADHD group also had a slower rate of prefrontal cortical thinning during late childhood and adolescence (Shaw et al., 2006). Applying the same longitudinal methods to typically developing children with varying levels of hyperactivity and impulsivity but no diagnosis of ADHD, children with higher symptom levels also demonstrated a slower rate of cortical thinning in several regions: predominantly in prefrontal cortical regions, bilaterally in the middle frontal/premotor gyri, extending down the medial prefrontal wall to the anterior cingulate; the orbitofrontal cortex; and the right inferior frontal gyrus (Shaw et al., 2011). The rate of cortical thinning was linked to the severity of symptoms, mirroring the slower rate of cortical thinning in adolescents with ADHD, who demonstrated the slowest rate. Similar to the findings from epidemiologic studies (Lubke et al., 2009), the results lend neurobiological support for viewing ADHD diagnoses dimensionally, lying at the extreme end of a continuum of symptoms, rather than as discrete categories, since typically developing children with symptoms but no diagnosis demonstrated similar neurodevelopmental changes in the brain (Shaw et al., 2011).

Despite the findings of group differences, structural imaging remains ineffective in its use as a clinical diagnostic tool at the individual patient level. However, early structural imaging findings were also found to relate to functional impairments in children with ADHD (Casey et al., 1997). Efforts to explore structure–function relationships have been greatly expanded through functional imaging studies.

Functional Imaging Studies

Early functional imaging modalities include single photon emission computed tomography (SPECT), first used in the 1950s, and positron emission tomography (PET), which originated in the 1970s. SPECT is an imaging method that uses injected or inhaled radiopharmaceuticals, such as xenon-133 or iodine-123, that distribute throughout the body, including the brain, and emit gamma rays as they decal; higher blood flow, and therefore higher amount of radioactive tracer, occurs in more highly active brain areas which is quantified by SPECT imaging. PET is an imaging method that uses injected or inhaled radiopharmaceuticals that emit positrons during decay which are detected by PET imaging; methods may be flow dependent although others measure cerebral metabolism rates. The majority of SPECT studies in ADHD have had methodological concerns, such as lack of or an inadequate control group. Among the studies of better design, findings include decreased striatal perfusion and increased regional cerebral blood flow after methylphenidate administration in dorsolateral prefrontal cortex, caudate, and thalamus in previously treatment-naïve children and adolescents with ADHD (Bush et al., 2005). A PET study of adults with ADHD reported significantly decreased global cerebral glucose metabolism of 8.1% (Zametkin et al., 1990). Although there were concerns about gender differences affecting the results, separate gender analyses and another study suggest that global metabolism is likely reduced in ADHD (Bush et al., 2005).

The use of PET and SPECT remains limited due to lack of ethical justification for radiopharmaceutical exposure in healthy children and/or volunteers. PET studies have been limited mainly to adults and a few studies of adolescents. SPECT also has poor spatial and temporal resolution. PET and SPECT have largely been replaced by functional MRI (fMRI, imaging technique that uses the blood-oxygen-level-dependent contrast to image the change in blood flow (hemodynamic response) related to energy use by brain cells; allows for inference of the regions of brain activation involved during a cognitive task), but continue to be used for drug and neurotransmitter transporter studies (Bush et al., 2005). Other techniques used to study ADHD include magnetic resonance spectroscopy, a noninvasive MRI-based method to quantify neurochemicals that might be abnormal in ADHD, and electrophysiologic methods such as quantitative electroencephalogram and event-related potentials. These methods are beyond the scope of this chapter and are not described in detail here due to their lack of spatial resolution.

fMRI has been paired with both cognitive tasks and the resting state to identify brain regions that are normally involved in attention, cognition, and various executive functions, and potentially abnormal in ADHD. We first review studies on the roles of cortical areas and then review neurocircuitry models between prefrontal cortex and subcortical regions in the subsequent section.

Cortical Dysfunction

Cingulate, frontal, and parietal cortical regions have been implicated in the pathophysiology of ADHD (Bush, 2011). These regions have been described as part of a cognitive-attention network in ADHD; in addition, striatum, premotor areas, thalamus, and cerebellum serve as nodes within parallel networks of attention and cognition. Cingulate subdivisions of dorsal anterior midcingulate cortex (daMCC, also previously referred to as the anterior cingulate cortex or ACC), dorsolateral prefrontal cortex, and ventrolateral prefrontal cortex have been studied for their individual contributions to pathogenesis of ADHD.

daMCC serves critical roles in a variety of cognitive processes, including attention, cognitive processing, target detection, novelty detection, response selection, response inhibition, error detection, and motivation. Given the wide variety of functions subserved by daMCC, it is relevant to reward/motivation and cognitive theories of ADHD as it may help modulate adjustments in behavior by influencing feedback-based decision making. Hypofunction of the daMCC in children with ADHD compared to healthy controls has been found in a number of fMRI studies using a variety of response inhibition and timing tasks (Bush, 2011). Findings of hypoactivation of daMCC were confirmed in a meta-analysis of neuroimaging studies, which also identified hypofunction of a wider network of regions, including dorso- and ventrolateral prefrontal cortex, superior parietal cortex, caudate, and thalamus (Dickstein et al., 2006). Other imaging modalities such as PET and event-related potential studies have also confirmed daMCC hypofunction in ADHD (Bush, 2011).

Studies of lateral prefrontal cortex have focused on dorsolateral and ventrolateral prefrontal cortex, as these regions are implicated in functions affected in ADHD such as vigilance, selective and divided attention, attention shifting, planning, executive control, and working memory (Bush, 2011). Smaller volumes in these regions in ADHD have been found in structural imaging studies. fMRI studies have also found dysfunction in dorso- and ventrolateral prefrontal cortex using tasks that tap response inhibition (Bush et al., 2005). Meta-analysis that focused only on response inhibition tasks identified ventrolateral prefrontal cortex, daMCC, parietal cortex, caudate, and precentral gyrus, but not dorsolateral prefrontal cortex, suggesting that abnormalities in dorso- and ventrolateral prefrontal cortex may contribute to ADHD in different ways (Dickstein et al., 2006).

The parietal cortex plays important roles in attention and spatial processing, specifically in attention allocation. Although the parietal cortex has been less well studied compared to other cortical areas, a number of functional imaging studies have identified parietal hypoactivation in children with ADHD during a variety of tasks, including a spatial working memory mental rotation task, task switching, mental rotation/spatial processing, and sequential finger tapping (Bush, 2011). Although hypofunction may represent primary abnormality in the parietal cortex, it may also reflect abnormal input from regions connected to it (Bush, 2011).

It has been proposed that the multiple functions subserved by the cortical regions reviewed may be subdivided into the following primary roles: dorsolateral prefrontal cortex, overall planning and goal-setting; ventrolateral prefrontal cortex and daMCC, inhibition of excessive or inappropriate motor behavior; parietal cortex, target detection and attention shifts; and daMCC, integration of information from these inputs and execution of plans by modifying behavior moment-to-moment. Hence, any dysfunction within these regions could lead to the behavioral manifestations of ADHD – inattention due to inability to detect targets or shift attention appropriately; hyperactivity due to failure to inhibit motor activity or use reward-and-error feedback to modify behavior; and impulsivity due to inability to encode motivational goals and/or pursue long-term goals over short-term goals (Bush, 2011). These cortical regions interact with other brain regions, including subcortical regions. We next review links among prefrontal cortex, striatum, and cerebellum.

Cortical and Subcortical Neurocircuitry Dysfunction

The prefrontal cortex has long been thought to exert control over behavior, and is especially important in cognitive control, or the ability to flexibly adjust behavior to changing circumstances. Inputs to and from prefrontal cortex are also vitally important to various functions; hence studies have focused on circuits to and from prefrontal regions. The main prefrontal cortex circuits implicated in ADHD include (1) dorsal frontostriatal, linked to cognitive control; (2) orbitofrontostriatal, linked to reward and motivation; and (3) frontocerebellar, linked to timing and building temporal expectations (Durston et al., 2011). These circuits interact with each other through spiraling loops in the striatum and connections from the cerebellum to the prefrontal cortex and striatum, but also have many more connections within circuits than between circuits.

The dorsal frontostriatal circuit comprises reciprocal connections among the striatum, thalamus, and prefrontal areas, and is critical for cognitive control. Functional imaging studies have shown differences in frontostriatal activity during cognitive control tasks (Dickstein et al., 2006; Durston et al., 2011). Additional support for the importance of connections between prefrontal cortex and striatum has been found in typical development, in which greater microstructural organization of white matter tracts predicted developmental improvements in cognitive control (Liston et al., 2006).

The orbiotofrontostriatal circuit comprises loops between ventral striatum and orbitofrontal cortex and is implicated in reward processing. It has been proposed that differences in sensitivity to reinforcement lead to changes in motivation, ultimately resulting in ADHD symptoms. Decreased ventral striatal activation in adolescents and adults with ADHD in anticipation of reward has been reported in three fMRI studies (Durston et al., 2011). It has been proposed that hypoactivation in response to reward might lead to increased impulsive reward-seeking behavior in ADHD (Durston et al., 2011).

The frontocerebellar circuit includes projections from the cerebellum via the thalamus to many areas of the prefrontal cortex, although there are also likely more direct connections between basal ganglia and cerebellum as well. The cerebellum has long been recognized for its roles in motor control and coordination, but now has also been found to have a role in cognitive functions and learning (Durston et al., 2011). fMRI studies have found attenuated cerebellar activation in ADHD during cognitive tasks tapping cognitive control, working

memory, and timing as well as resting-state fMRI (Durston et al., 2011).

Summary

Dysfunction in several brain regions and neural circuits has been identified in ADHD. It has been proposed that many pathways may lead to the clinical phenotype of ADHD and that perhaps identification of specific prefrontal–subcortical circuits could be used to subtype ADHD (Durston et al., 2011).

Connectivity Studies

The study of connections between prefrontal and subcortical regions, among others, in ADHD has been enhanced by relatively new imaging techniques including diffusion tensor imaging (DTI) and resting-state fMRI. These techniques allow for study of both structural and functional connectivity.

Structural Connectivity

DTI is an MRI technique that generates quantitative measures of white matter microstructure in the brain. It quantifies anisotropic diffusion, the degree to which diffusion is greater in one direction than another, to approximate microstructural integrity of white matter (Feldman et al., 2010). Since myelinated axons restrict water diffusion such that water diffuses more readily in parallel rather than perpendicular to a white matter tract, anisotropy is thought to be proportionate to the degree of myelination, orientation, regularity, and density of axons in a tract. Hence, higher fractional anisotropy (FA, a primary outcome measure generated by DTI which is a ratio ranging from 0 to 1; represents the degree to which diffusion is anisotropic. High FA values indicate that diffusion is greater in one direction than others, whereas low FA values indicate that diffusion is nearly equal in every direction) is thought to reflect more mature or healthy white matter.

DTI studies in children and adolescents with ADHD yield mixed results with findings of reduced (Nagel et al., 2011; Ashtari et al., 2005), increased, or mixed FA (Peterson et al., 2011; Davenport et al., 2010) in multiple regions and/or tracts compared to controls. A variety of tracts have been identified as abnormal in ADHD, including frontostriatal projections, superior longitudinal fasciculus, and tracts involving the cerebellum, corpus callosum, basal ganglia, anterior cingulate, and corticospinal tract (Liston et al., 2011; Konrad and Eickhoff, 2010). Out of 8 DTI studies, 7 studies found structural connectivity deficits in frontostriatal projections (or anterior corona radiata) in ADHD compared to control subjects, whereas 6 of 9 DTI studies that examined the superior longitudinal fasciculus found structural connectivity deficits (Liston et al., 2011). Two studies of adult ADHD report reduced FA in the superior longitudinal fasciculus.

DTI studies have been performed in children born preterm as this population is at high risk for both overt and subtle, diffuse white matter injury. Children born preterm are also at elevated risk for ADHD, and studies often report high levels of attention difficulties even if children do not meet full criteria for the disorder (Johnson and Marlow, 2011). Hence, children born preterm serve as a neurobiologic risk model for ADHD and associated problems. DTI studies of children and adolescents born preterm have found significant associations between white matter properties and attention within preterm samples; regions of association include the corpus callosum and bilateral internal capsules (Skranes et al., 2007; Nagy et al., 2003), left external capsule, bilateral inferior fasciculi, left middle fasciculus, and right superior fasciculus (Skranes et al., 2007). Another study found that both attention and internalizing problems, such as anxious and withdrawn symptoms, were associated with white matter FA in several distributed and overlapping regions, suggesting common underlying neurobiology for behavioral symptoms in this high-risk population (Loe et al., 2013).

An innovative approach to study structure and function combines DTI with fMRI by applying fiber tractography to reconstruct white mater tracts and assess the role of connectivity within anatomically specified projections. A study of children with ADHD and their parents used fMRI and DTI tractography during a cognitive control task. Results showed that tract-specific connectivity in white matter projections from the striatum to the prefrontal cortex correlated positively with activity in the caudate nucleus and inferior frontal gyrus during the cognitive control task (Casey et al., 2007). In addition, individual differences in connectivity as measured by FA predicted performance for children with ADHD and their parents but not control subjects (Casey et al., 2007). Other regions identified as having abnormalities in ADHD using fiber tractography and other DTI measures of connectivity include frontostriatal projections, superior longitudinal fasciculus, cingulum bundle, and cerebellar peduncles (Liston et al., 2011).

The DTI studies described above are heterogeneous in terms of different analytic approaches, such as whole brain, region of interest, and tract-based statistics. Alterations in superior longitudinal fasciculus and frontostriatal white matter appear to be the consistent findings at this time (Liston et al., 2011).

Functional Connectivity

Functional connectivity estimates the strength of long-range connections by inferring the aggregate strength of functional connections between two areas of cortex. It is often defined as the temporal correlation or coherence of spatially remote neurophysiological events (Konrad and Eickhoff, 2010). Although correlated activity might result from a third area that drives activity between two areas or reflect multisynaptic relays across multiple intermediate areas of cortex, it is generally thought that estimates of structural connectivity correlate well with functional connectivity (Liston et al., 2011).

Two general approaches for assessing functional connectivity are (1) the task-based fMRI approach and (2) resting-state fMRI. The task-based approach measures correlated activity in different cortical areas that are coactivated when a specific function is performed during a task (i.e., response inhibition during a go-/no-go task). Five task-based studies in children with ADHD that have examined group differences in correlation strength between regions found connectivity deficits (Liston et al., 2011). One study found reduced coupling in frontocerebellar and frontoparietal circuits during a combined interference and time discrimination task. Two studies found that methylphenidate normalized or ameliorated connectivity deficits and improved behavioral performance during a task

requiring selective attention and suppression of competing information and a rewarded continuous performance task (Liston et al., 2011). In resting-state fMRI, the subject is imaged 'at rest' with no specific task to perform. A specific default mode network (DMN) has been identified from resting-state fMRI, which includes a large and replicable network of brain regions associated with task-irrelevant mental processes and mind wandering. The DMN comprises the precuneus/posterior cingulate cortex, the medial prefrontal cortex, and the medial, lateral, and inferior parietal cortex (Konrad and Eickhoff, 2010). During rest, the DMN shows higher activity and stronger functional connectivity than during externally driven tasks. DMN activity is attenuated, but not extinguished during transition from rest to task states. Stronger deactivation of the DMN has been associated with increased task difficulty. DMN activity is negatively correlated with lateral prefrontal cortex activity during attentional and executive function tasks, and it has been proposed that failure to suppress DMN activity sufficiently interferes with task performance (Liston et al., 2011; Konrad and Eickhoff, 2010). In contrast with the DMN, a second network consisting of dorsolateral prefrontal cortex, intraparietal sulcus, and the supplementary motor area has been identified as active during tasks that require active allocation of attentional resources. These regions have been associated with increased alertness, response preparation, and selective attention in a manner that is largely independent of the specific task. This network is referred to as the 'task-positive' frontoparietal network. It has been found to be anticorrelated (negative correlation in which one value increases as the other decreases; used to describe resting state fMRI data and generally observed between competing neural systems) with the DMN, such that the DMN is attenuated when there is task-specific activation of the task-positive network and vice versa (Konrad and Eickhoff, 2010). Studies using resting-state fMRI in ADHD in general have shown that for both ADHD and control groups, DMN activity is anticorrelated with activity in regions that have important roles in cognitive control such as ACC (Castellanos et al., 2008; Liston et al., 2011). However, the ADHD group often shows a weaker relationship between the DMN and regions implicated in cognitive control, consistent with failure to suppress the DMN activity during tasks requiring cognitive control.

Summary

Relatively new methods of analysis to assess functional connectivity suggest that there are altered interactions between networks implicated in ADHD or changes in DMN network activity. Varied tasks, methods, and analytic strategies do not allow meta-analytic review of connectivity studies at this time. Although correlations do not equal causality, early work showing improvements in both behavioral performance and connectivity with stimulants suggests that these connectivity deficits may play a role in ADHD symptomatology (Liston et al., 2011).

Neurotransmitter Systems

Dysregulation of dopamine and noradrenaline has been implicated in the pathophysiology of ADHD, and these catecholamines are affected by first-line pharmacotherapy with psychostimulants such as methylphenidate and dextroamphetamine (*see* Neurotransmitters). The neurotransmitters modulate activity in fronto-striato-cerebellar circuits, affecting executive functions that are often deficient in ADHD. PET and SPECT studies have been used to assess neurotransmitters directly *in vivo*, at baseline or in response to medication. However, the precise neurobiological mechanisms underlying pathogenesis and treatment remain poorly understood.

Dopaminergic System

The dopamine transporter (DAT) is a protein that spans the cell membrane and serves to regulate dopamine by pulling it from the synaptic space into the presynaptic neuron. There are at least five dopamine receptors on the postsynaptic neuron, each of which is coded by a distinct gene (D1–D5). Receptor D_4 has been of particular interest in ADHD because of polymorphisms in a region of tandem repeats.

Imaging studies of the DAT have yielded mixed results, with early studies showing increased density in ADHD and more recent studies in medication-naïve adults with ADHD showing reduced DAT and D_2/D_3 receptor availability in subcortical regions (Del Campo et al., 2011). These differences have been attributed to differences in medication history as well as genetic differences, including polymorphism of the DAT1 gene (Del Campo et al., 2011). Limitations of imaging studies of dopamine receptors include the low affinity of radiotracers, which restricts the focus to brain areas high in D_2/D_3 density, such as the striatum, rather than prefrontal cortex where low D_2/D_3 receptor density and inadequate neurotransmission may contribute to ADHD. Studies to examine other dopamine markers also show disparate results due to many methodological and individual patient factors that influence expression of dopaminergic markers (Del Campo et al., 2011).

PET studies have confirmed methylphenidate blockade of DAT, resulting in increased extracellular dopamine in the striatum. Levels were not correlated with blockade, indicating that other factors contribute to dopamine release. Animal studies using microdialysis also show increases in dopamine in extrastriatal areas such as frontal cortex with stimulant administration. In the frontal cortex, increased dopamine levels after stimulant administration are attributed to the noradrenaline transporter (NAT), which has high density in the frontal cortex and low density in the striatum, converse to DAT density in those areas. Dopaminergic systems in frontostriatal and nigrostriatal networks (midbrain to striatum) and interactions between prefrontal cortex and subcortical systems are also the focus of investigations to understand the therapeutic effects of psychostimulants (Del Campo et al., 2011).

Noradrenergic System

Noradrenaline has long been implicated in pathophysiology of ADHD but is less well studied than dopamine. Noradrenaline is thought to exert effects primarily in prefrontal cortex as there is sparse noradrenergic innervation in the striatum. Noradrenaline projections to prefrontal cortex originate from the locus

coeruleus. Multiple pharmacologic agents for ADHD have important effects on noradrenaline transmission, including methylphenidate, dextroamphetamine, buproprion (an indirect dopamine and noradrenaline agonist), tricyclic antidepressants, guanfacine (an alpha-2 receptor antagonist), and atomoxetine (selective noradrenaline reuptake inhibitor) (Del Campo et al., 2011). Molecular imaging of the noradrenaline system has been limited due to lack of suitable tracers, although recent work using PET shows that clinical doses of methylphenidate significantly reduce NAT availability in a dose-dependent manner in dense receptor regions, including locus coeruleus, raphe, hypothalamus, and thalamus (Del Campo et al., 2011).

Psychostimulant medications are the first-line medical treatments for ADHD. Methylphenidate blocks reuptake of dopamine and noradrenaline, thereby increasing extrasynaptic transmitter levels. Dextroamphetamine also inhibits reuptake of dopamine and noradrenaline, but also increases extracellular levels by promoting efflux of the neurotransmitters into the extraneuronal space and inhibiting catabolic activity of monoamine oxidase (Del Campo et al., 2011). Initially, the 'calming effect' of psychostimulants on behavior was thought to be a 'paradoxical' reaction unique to individuals with ADHD; however, the behavioral-calming and cognition-enhancing effects of low and clinically relevant doses of psychostimulants were observed in humans without ADHD as well as animals (Berridge and Devilbiss, 2011). The effects of psychostimulants on prefrontal cortex-dependent behavior and cognitive processes are observed acutely and without tolerance that occurs with many medications after extended treatment (Berridge and Devilbiss, 2011). Research on the mechanisms underlying cognition enhancing and therapeutic effects of low-dose stimulants indicates that low-dose stimulants preferentially increase extracellular levels of catecholamines in prefrontal cortex and preserve phasic signaling of catecholamine neurons (Berridge and Devilbiss, 2011). There are regionally selective neurochemical actions of low-dose stimulants and enhanced neuronal responding to afferent signals within prefrontal cortex. This regionally specific effect on neuronal signal processing in prefrontal cortex contrasts sharply with the widespread action of higher and behaviorally activating doses of stimulants, which also results in profound suppression of prefrontal cortex neuronal signaling. In addition, rather than acting directly on dopamine as a primary target, pharmacologic treatments for ADHD appear to involve both dopamine and noradrenaline acting at postsynaptic alpha-2 and D_1 receptors in the prefrontal cortex (Berridge and Devilbiss, 2011).

The evidence that stimulants improve core symptoms of ADHD and exert effects at the neurobiological level is well-established. However, individual variation in treatment response has prompted pharmacogenetic studies to identify genetic predictors of treatment effects. The underlying premise of pharmacogenetics is that by studying individual candidate genes, failure of or variation in response can be linked to specific gene variants that affect receptors, transporters, or drug-metabolizing enzymes (Froehlich et al., 2010). Pharmacogenetic studies in ADHD have focused on catecholamine-related polymorphisms that affect the DAT gene and dopamine receptor D_4 (DRD4). For example, polymorphisms in a variable number tandem repeat in the 3′-untranslated region of the DAT gene have been studied for their possible role in predicting treatment response since DAT inhibition is a primary mechanism of methylphenidate. Other studies have focused on polymorphisms in DRD4, which regulates dopamine synthesis, release, and neuron firing rate. However, results from DAT and DRD4 studies have been mixed in terms of links between various alleles and methylphenidate response (Froehlich et al., 2011b). Other genes of interest include the adrenergic alpha-2A receptor, catechol-O-methyltransferase, which catabolizes dopamine and norepinephrine, D_5 receptor, NAT protein 1, and synaptosomal-associated protein.

Results have been inconsistent across studies with disparate results attributed to small samples; variation in study design (open label vs randomized controlled trials); and differences in samples, outcome measurements, and dosing regimens (Froehlich et al., 2010). A recent, well-designed study of stimulant-naïve children with ADHD examined the role of four catecholamine-related candidate genes in moderating methylphenidate dose response (Froehlich et al., 2011b). This randomized, double-blind, crossover trial of long-acting methylphenidate included parent and teacher evaluations of response to placebo and three methylphenidate dosage levels. They found significant gene-by-dose interactions for hyperactive-impulsive symptoms for DAT and DRD4 polymorphisms. The DAT 10-repeat allele and DRD4 7-repeat allele have each been associated with ADHD risk in other studies, whereas the more common DRD4 4-repeat allele is considered low risk. In this randomized trial, children who lacked the DAT 10-repeat allele showed greater improvement in symptoms with increasing dose compared with 10-repeat carriers. Children who lacked the DRD4 4-repeat allele showed less improvement across doses compared with 4-repeat carriers (Froehlich et al., 2011b). The findings, in which children lacking the DAT 10-repeat allele and those with the DRD4 4-repeat allele had more robust response to methylphenidate compared to other genotypes, are consistent with an improved response for the ADHD-susceptibility low-risk alleles (Froehlich et al., 2011b). The results suggest that DAT and DRD4 polymorphisms may be associated with individual variability in dose response to methylphenidate. With replication, exciting findings such as these could be used to guide tailored prescribing in an era of personalized medicine in the future.

Other Interactions with Neurobiology

Risk factors associated with ADHD include environmental toxins such as lead, pesticides, and industrial chemicals; nutritional factors such as low child zinc and omega-3 fatty acid levels; and lifestyle and psychosocial factors, such as maternal stress, early trauma, and institutional care (Froehlich et al., 2011a). The mechanisms by which these factors exert ADHD-related neurobehavioral effects go through changes to the neurobiological systems described above. For example, lead exposure leads to disruption of synapse formation and

derangements to the brain dopaminergic system (Froehlich et al., 2011a). Twin and family studies of ADHD indicate high heritability, on the order of 0.6–0.8; these figures also reflect that environmental influences also play an important role in disorder susceptibility (Froehlich et al., 2011a). New studies of gene–environment interactions in ADHD may elucidate how both genetics and environmental influences contribute to ADHD. By including gene and/or environmental factors in neuroimaging studies, we may also be able to determine the multiple pathways contributing to neurobiological differences and manifestations of ADHD.

Conclusions

Our understanding of ADHD has greatly evolved since it was first described in the medical literature as a 'defect of moral control.' Recent advances in neuroscience, coupled with genetic, environmental, and psychopharmacology studies, shed light on the neural basis of the disorder and may provide guidance for prevention and treatment. Structural, functional, and connectivity imaging studies of the brain have greatly contributed to our understanding of the networks involved in pathogenesis of the disorder. However, these neuroimaging methods are ineffective at the level of individual diagnosis and treatment and remain research tools at this time. Genetic evaluations may ultimately be able to identify which individuals with ADHD will be responsive to specific medications to improve function.

Abstract

Over the last three decades, cognitive neuroscience has contributed outstandingly to research on attention. Selective attention is a key mechanism the brain uses to face the enormous flow of stimuli coming from the environment, with the ultimate purpose of focusing on the relevant object, thus achieving goal-directed behavior. Classical studies in monkeys and recent research using novel techniques in humans and other animals have been integrated, thereby contributing to the development of neural and functional models of explanation of several mechanisms through which visual selective attention is deemed to operate.

Selective attention is a key mechanism the brain uses in order to make efficient object recognition and to focus on the relevant stimulus, with the ultimate purpose of achieving coordinated, goal-directed behavior. Indeed, the flow of inputs that is constantly available from the environment to our sense organs is far greater than the brain can handle and cope with, and cognitive psychology research has clearly established that our perceptual system is severely limited in its capacity to fully process and identify more than one object at a time. Moreover, our response system is limited inherently in its ability to perform concurrent actions on a large number of objects: we can only gaze at one object at a time to align it with the fovea of the retina, and reach at most to two objects. Selective attention allows the brain to select the most important aspects of the sensory scene and filter out those that are irrelevant or potentially interfering with the goal. Perceptual experience of the sensory world critically depends on attention. Selected objects can enter perceptual awareness, guide our choices and actions, and undergo memory storage, whereas ignored and irrelevant objects are often left at the margins of our consciousness.

For several decades, selective attention has been studied at the psychological level. More recently, behavioral research has been strengthened by a variety of neuroscience approaches as diverse as single-neuron recordings in monkeys, functional neuroimaging and event-related potentials in humans, lesion studies in neurological patients, and, lately neural-network models. This interdisciplinary and convergent effort is beginning to reveal how the brain activity is regulated through attention. Due to its essential role in building and gating object representations, this article will focus mainly on selective visual attention and review some recent experimental advances in understanding the neural underpinnings and mechanisms of this cognitive function.

Multiple Visual Pathways

The neural representations of visual objects have been demonstrated by contemporary neuroscience to be highly distributed. Visual inputs activate almost simultaneously a variety of cortical and subcortical regions within the brain. Among visually responsive structures are 30 or more separate cortical areas, which appear to be organized within two major parallel pathways, or streams (Ungerleider and Mishkin, 1982; Reynolds and Chelazzi, 2004; Connor et al., 2007). Each visual stream begins with the primary or striate visual cortex (area V1) and then involves multiple areas of the secondary and extrastriate visual cortices beyond V1. One of the pathways, the ventral stream, leads toward the inferior temporal (IT) cortex, and is crucial for object perception and recognition (the 'what' pathway). The other pathway, the dorsal stream, is directed into the posterior parietal cortex and is mostly concerned with spatial localization and action (the 'where' or 'how' pathway). Physiologically, the processing of visual information appears largely hierarchical within each cortical pathway, whereby object representations are synthesized with level of complexity. Specifically, the latency of visual responses, the size of the receptive field (RF), and the complexity of neuronal tuning properties increase steadily as one proceeds from one area to the next in the processing hierarchy. Anatomically, two types of connections between areas can be identified: (1) feed-forward connections that relay information from lower to higher visual areas in each pathway and (2) feedback connections that provide recurrent signals from higher to lower levels of processing. As described below, feedback, re-entrant connections from parietal and frontal areas, may form the anatomical basis of top-down attentional signals that modulate activity elsewhere in the visual system.

The Anatomical Locus of Selective Attention

Historically, the parietal lobe has been viewed as central in visual selection. Damage to this region commonly produces unilateral neglect, a deficit in perceiving and interacting with events on the contralesional side of space, which has often been explained as a difficulty in directing attention to that side. Patients with left neglect, for example, fail to complete the left half drawings, or to read the left side of words or passages of text. The attentional nature of neglect is well shown by the observation that the deficit is greatly exaggerated by competing

inputs on the intact, ipsilesional side ('extinction'). In fact, recent evidence based on large series studies indicates that neglect and extinction may follow a wide variety of unilateral lesions, both cortical and subcortical. This indicates a multiplicity of competitive systems modulated by attention and behavioral relevance, rather than a single anatomical level at which attention affects processing.

Data from lesion studies in monkeys are consistent with this conclusion. Indeed, different methodologies, such as single-unit recording, event-related potential (ERPs), functional imaging, and lesion studies provide converging evidence that attention can affect neuronal activity in most of the extrastriate visual areas where such modulation has been investigated. Paradoxically, many electrophysiological reports suggested that the processing of attended and unattended items does not differ in primary visual cortex. Monkey physiology in the past yielded conflicting results in this regard. In some studies, approximately 30% of V1 neurons revealed some form of attentional modulation. However, in a pioneering study (Roelfsema et al., 1998), monkeys were trained on an ingenious task in which animals had to trace one of two curves – the attended curve – while maintaining fixation. The firing rate of V1 neurons was found to be significantly higher when the receptive field was on the curve that needed to be traced, than on the distracting curve. The long latency of the enhancement (about 200 ms) suggested that this effect might be mediated by feedback processing from higher-order areas in the visual hierarchy.

Functional magnetic resonance imaging (fMRI) studies in humans have also shown that spatial attention is indeed capable of modulating neuronal activity in V1. One study compared the magnetic resonance signals in central and peripheral parts of V1 while subjects were either attending to a rapidly presented series of letters in the center of the visual field or performing a direction-of-rotation discrimination task on a peripheral rotating disk (Somers et al., 1999). In striking contrast with previous imaging studies, substantial increases in activity were found in V1 regions corresponding to the attended stimulus and decreases in regions representing the unattended stimulus. Together, these studies demonstrated that, depending on the visual task, attentional modulation of responses does indeed occur in the primary visual cortex. For the region of V1 representing the attended part of the visual field, neuronal responsiveness increases; conversely, when attention is directed away from a particular location there appears to be a consequent decrease in responsiveness in the retinotopically corresponding V1 region.

How can these recent findings be reconciled with previous failure to find attentional modulation in V1? One explanation is that, in the earlier studies, the tasks were not sufficiently demanding. In the new studies, stimulus parameters were chosen so that tasks were difficult and only 70–90% correct responses were achieved. Alternatively, it is possible that some techniques, like ERP recordings, may reflect only initial, feed-forward processing in V1. Apparently, the early part of the visual response of V1 neurons is unaffected by attention, as single-unit studies have shown. In contrast, the relatively poor time resolution of fMRI measurements would capture both early feed-forward processing and later top-down attentional influences from higher visual areas.

How Does Visual Selective Attention Work?

According to a traditional view, visual attention has been viewed as a mental spotlight or zoom lens that illuminates stimuli in selected regions of space, thus easing their access to higher processing centers (Posner, 1980). Visual attention would be inherently spatial in nature, so that objects are found by rapidly shifting the attentional spotlight from one location to another. The canonical view also poses that attention is mainly controlled by a unified, topographical 'master' map located in the parietal cortex and associated spatial processing structures. However, several recent findings suggest that any effect of attention is best explained in terms of competitive interactions among the neural representations of objects present in the visual field, as outlined by the Biased Competition Model of visual attention (Desimone and Duncan, 1995). According to this model, (1) multiple inputs falling within the same RF compete for controlling the neuron's firing rate at all levels of the visual system (e.g., Zoccolan et al., 2005), and (2) different mechanisms can tip the competitive balance in favor of one stimulus' representation over the others, thus causing the neuron's firing to be determined by the selected object (e.g., Reynolds and Desimone, 2003).

At the behavioral level, competition is reflected in the loss of accuracy or slowing in reaction time that result when subjects are required to identify multiple stimuli at once, rather than a single object. At the physiological level, single-unit recording studies in monkeys have shown that responses to two stimuli that fall inside a single RF (or its surrounding) of visual cells are smaller than responses to either stimulus in isolation (Reynolds et al., 1999). This indicates that multiple stimuli in the visual field, effective or ineffective for that cell, are not processed separately from each other but rather they interact in an inhibitory, suppressive fashion. In agreement with this result, an fMRI study in humans (Kastner et al., 1998) has shown that neural responses from visual areas are lower when stimuli are presented simultaneously than when identical stimuli are presented one after the other in the same locations. The reduced activation in the simultaneous condition may reflect sensory suppression among multiple concurrent visual stimuli ('repetition suppression'; Kanwisher and Wojciulik, 2000; Kastner and Ungerleider, 2000; Vuilleumier et al., 2005).

Competitive interference between stimuli has been especially observed in ventral stream areas. However, there is also evidence for sensory competition in structures associated with the dorsal stream, for example, in the frontal eye field (FEF) and in areas MT and MST. Here, cells respond best to stimuli motion, that is, to particular 'preferred' direction across the RF, but respond weakly or not at all to stimuli moving in the opposite or 'null' direction. Treue and Maunsell (1996) found that the response to an otherwise optimal stimulus (i.e., moving in the cell's preferred direction), placed within the RF of an MT neuron, was critically reduced by the addition of a second, nonpreferred stimulus at a different location in the same RF. Recently, computational neuronal models have been developed to predict different effect of neuronal firing. One of these, the Normalization Model of Attention (Reynolds and Heeger, 2009), posits that the attention multiplies the excitatory drive for the neuron in a selective manner, prior to

normalization (i.e., its division by the sum total drive across the neuronal population).

Bottom-Up and Top-Down Biases

Competitive interactions between neuronal populations encoding different visual objects can be modulated and solved by virtue of bottom-up and top-down biases, such that neurons encoding one object win out over the competition and that object receives further processing in the brain. Bottom-up factors refer to largely automatic and unconscious processes that operate early in vision and presumably contribute to perceptual 'pop-out' phenomenon – the quick and effortless detection of a unique item (for instance, based on luminance contrast) on a homogeneous background, at no increasing cost as a function of the number of distractors (Nothdurft, 2000). A stimulus ineffective, due to its features, in driving a visual response from a given neuron, may nonetheless be effective in determining the response, due to its salience. Bottom-up biases are thought to be mediated by hard-wired neural mechanisms, such as the center-surround structure of RFs found in many areas of the visual system. However, competition among visual neurons can also be biased by top-down cognitive influences, in which objects that meet the requirements of the current task are voluntarily selected for focal attention. For instance, top-down biases allow you on one occasion to search efficiently for your mug on a desk cluttered with many objects, while on another occasion you might search the same complex visual scene for your pencil. Top-down biases, as the name implies, are imposed on low-level sensory processes by higher-level control mechanisms, and are probably mediated by extensive feedback connections from higher areas (parietal and frontal) to low-level sensory areas. It is to these processes and their contribution to resolve competition between stimuli that the article will now turn.

What Does Attention Select?

In contrast to the spotlight model of visual attention, a central tenet of the Biased Competition Model is that the feedback bias from higher areas is not purely spatial. Depending on the context, different visual features – spatial location, color, shape, or motion – can be used to direct attention and assign limited processing resources to a particular object. Some psychologists have arrived at the notion of attentional template, a flexible, short-term description, formed to suit the task at hand, that can be used to give a competitive advantage to visual inputs matching that description. The attentional template can specify any property of the relevant object. Spatial location is, therefore, only one among many features that can contribute to the attentional template. For example, consider a subject that is asked to search for and report numbers colored in red and to disregard numbers in other colors. Following this instruction, neurons selective for red inputs are primed or preactivated in visual areas coding colors, such that a stimulus that possesses the behaviorally relevant color is processed preferentially over others. Information specifying the target of selection, be it spatial- or feature-based, is represented online in frontal networks while making the task ('working-memory'), and affects the activity of V4 neurons in a salience-based manner, even if with distinguishable time courses between spatial and visual processing (Hayden and Gallant, 2005).

Space-Based Selection

In the past, much research on the control of visual attention has focused on selection in space. In most behavioral studies, subjects covertly (i.e., without executing eye movement) direct their attention onto stimuli shown at a specific spatial location in the visual field, whereas distracting information is present at the other locations. Sensitivity has been shown to increase at attended versus unattended locations in the visual field, enhancing performance in terms of reduced reaction times and greater accuracy, and reduced at the distractor locations, suggesting that competition for focal capacity is biased toward objects at the attended region of space. A host of single-cell recording works in monkeys have reported that attention can increase the neural response to a visual stimulus when it appears at an attended location compared with when the animal attends to a different stimulus location. This selective enhancement effect, which increases with task difficulty and with the amount of visual clutter outside of the RF, has been demonstrated in numerous visual structures. These include primary visual cortex, areas V2 and V4, but especially dorsal stream areas implicated in visuomotor control, such as the lateral intraparietal area, the FEF, and the dorsolateral prefrontal cortex (Colby and Goldberg, 1998). Moreover, spatially directed attention also affects neuronal firing at subcortical level. For instance, enhanced visual responses were found in the lateral geniculate nucleus of the thalamus (McAlonan et al., 2008). In humans, brain imaging and ERP studies have reported similar findings. In these experiments, identical stimuli were presented on either side of fixation, while normal subjects focused attention to the left or right visual field. Results showed enhanced activity in extrastriate visual areas, generally lateralized to the hemisphere contralateral to the attended stimulus, in agreement with the fact that many visual areas have a predominantly crossed representation of the visual field (Kastner and Ungerleider, 2000). Overall, these findings suggest that top-down biases operate by increasing the input strength for stimuli at the attended locations. Most notably, however, these studies generally failed to find any effect of spatial attention on activity in human V1 (see above), and the above described effect of response enhancement is relatively large with stimuli of low contrast, whereas this tends to decrease with increasing contrast of the stimulus.

An alternative, not exclusive, possibility, however, is that spatial attention filters out distracting information when multiple stimuli appear simultaneously within the individual neuron's RF. Studies in extrastriate ventral areas V2 and V4, but also in dorsal areas MT and MST, have shown that, when monkeys attend to a stimulus at one location within the RF, competitive interference from stimuli at ignored locations within the RF is greatly attenuated or suppressed (Moran and Desimone, 1985). Apparently, the cell's RF 'shrinks' around the attended location, with unattended stimuli being filtered out. In addition, the effects of attention are much weaker when either the target or the distractor is placed outside the RF. Indeed, in such a configuration stimuli are no longer competing for the cell's response, thus reducing the need of

attentional biases. The suppressive mechanism of attention may explain why we have little awareness of unattended stimuli, and is highly consistent with the idea that spatial attention biases the sensory interactions among neurons, causing them to respond primarily to the attended stimulus.

In accordance with monkey neurophysiology, one fMRI study in humans showed that directing attention to one object in a cluttered visual scene reduces the sensory interference exerted by distracting stimuli at nearby locations (Kastner et al., 1998). Although attention can suppress irrelevant stimuli, it does not imply that it always does. According to one theory of attention, the extent to which spatial attention inhibits irrelevant information depends on the processing load imposed by the primary task, with stronger inhibition occurring when processing load is high. Consistent with this, an fMRI study by Rees et al. (1997) showed that neural responses to irrelevant moving stimuli, as registered in the motion-processing visual areas MT and MST, are much weaker when the primary task is difficult than when it is easy.

Nonspatial Feature-Based Selection

Although spatially directed attention has proven to be an excellent model system for investigating attentional mechanism, objects can be also selected by attention based on other, nonspatial, properties. For example, color can be used efficiently to control attention, particularly when there is a large hue difference between target and distractors. Neurophysiological studies in monkeys have considerably extended our understanding of feature-based processes for directing visual attention. In a single-neuron study in IT cortex, monkeys were instructed to perform a simple visual search task (Chelazzi et al., 1993, 1998, 2001). On each trial, a central cue was presented, followed by a blank delay period. At the end of the delay, an array of stimuli was presented and the monkey was rewarded to make a saccadic eye movement toward the stimulus matching the cue (target). The location of the target was not known in advance and thus selection could not be based on spatial information. Just like attention to location, attention to an object (nonspatial) feature was found to inhibit neuronal responses to irrelevant stimuli. Neurons in IT cortex showed an initial response if the choice array contained their preferred stimulus, without regard of the target identity. When the preferred stimulus was the eye movement target, the initial response remained high. However, when the preferred stimulus was an irrelevant, distracting stimulus in the array, the initial response was rapidly inhibited, long in advance of the onset of the saccade. Interestingly, neurons selective for the cue showed higher sustained activity during the delay. It has been argued that this tonic activity during the interval represents the neural correlate of the attentional template, which can be used to bias competition in favor of cells representing the target. Other neurophysiological studies also reported attentional modulation based on object features. Interestingly, studies that have used a single stimulus within the cell receptive field found facilitation of attended stimuli as well as inhibition of unattended stimuli.

Functional neuroimaging studies provided additional insight into feature selection. In a classic positron emission tomography study (Corbetta et al., 1991), subjects compared two successive visual displays, with reference to the color, shape, or speed of motion. Depending on the relevant visual feature, different extrastriate areas were active: attention to color led to enhanced visual response in area MT, whereas attention to shape and motion induced response enhancement in area V4.

Similar results have been reported using ERPs and fMRI. Together, these studies argue that selective attention to a particular visual feature enhances neural activity in areas selectively specialized for that attribute. Attention selection can also occur from whole object representations. In a recent fMRI study (O'Craven et al., 1999), two stimuli, a face and a house, were superimposed transparently in the same location. In each trial, either the face or the house oscillated back and forth. Subjects' attention was directed in different conditions to the face, the house, the direction of motion, or the spatial location of the stationary stimulus. As expected, different brain regions were activated depending on whether the relevant feature was the face (fusiform face area), the house (parahippocampal place area), or the direction of motion (areas MT and MST). Importantly, however, results showed that attention to one feature of an object enhanced the representation of other features of the same object, even when these features were completely irrelevant for the task. This 'cross-feature attention' phenomenon strongly suggests that attention selects entire objects, rather than selecting simple visual attributes and it evidences how it is easier to divide attention between different features of a single object than between features belonging to different objects (Duncan, 1984). In the case of a single object, for instance during a Stroop test (Stroop, 1935), choices must be guided by a selection of the relevant feature and the minimization of irrelevant ones. In the case of otherwise identical stimuli, responses of V4 neurons to them are modulated depending on the component feature of the stimulus being currently attended (after being cued), which could have been a specific color or orientation (Mirabella et al., 2007). The area V4 may be important in the process of converting selected feature information into a signal available to guide behavioral responses, suggesting that neurons in this area encode the behavioral response associated to the selected feature in a perceptually categorical fashion, instead of being a purely sensory area (Mirabella et al., 2007).

The Neural Mechanisms of Selection

Do attentional signals affect visual processing by facilitation of attended stimuli or by inhibition of irrelevant distractors, or both? One view suggests that attention exerts its influence by inhibiting unwanted stimuli early in visual processing, and by enhancing relevant information later on. The assumption underlying this view is that neurons in early visual areas respond at close to maximal rates to visual stimuli even during passive viewing, and therefore there is little room for response enhancement in early stages. In contrast, in higher visual areas, cells become less stimulus driven and more sensitive to behavioral relevance. Overall, recent single-unit and neuroimaging data do not support such a suggestion, and argue instead for a close interplay between suppressive and enhancing mechanisms at all levels of the visual system.

For example, a recent fMRI study reported that attention to a particular spatial location, in addition to an enhanced response to the attended visual stimulus, results in a widespread suppression of activity at all other locations (Smith et al., 2000). However, ERP studies have shown that the 'costs' of spatial cueing are associated with suppression of unattended inputs at an early stage, whereas the 'benefits' of cueing are associated with enhancement of attended stimuli at a later stage (Hillyard and Anllo-Vento, 1998). Thus, there is at least some suggestive evidence that suppression and enhancement may entail qualitatively different mechanisms, which operate at different levels of the visual pathways (Motter, 1993; Carrasco et al., 2004; Carrasco, 2006).

Top-down attentional signals may also affect visual processing by increasing the spontaneous (baseline) level of neural activity in the absence of any visual stimulation. Single-cell recording studies have clearly shown a substantial elevation of baseline activity for neurons in area V2 and V4, when the monkey was instructed to attend covertly to a location within the receptive field, even before the stimulus was presented there (Luck et al., 1997). The shift in baseline activity during spatial attention closely resembles the sustained, tonic activation found in IT neurons during visual search experiments. This increase in spontaneous firing rate is consistent with the idea of top-down feedback signals priming neurons coding the attended location of space. In a similar vein, several fMRI studies in humans have shown that during the expectation period preceding the arrival of a stimulus at an attended location, baseline activity increased in numerous extrastriate visual areas. The effect is spatially selective, as it occurs only in subregions of visual areas with a representation of the attended location; thus, it cannot be due to nonspecific arousal. Remarkably, an increase in baseline activity has been found even in the primary visual cortex during a demanding threshold detection task, and its magnitude was highly predictive of the subject's behavioral performance (Ress et al., 2000).

The Control of Visual Attention

A central issue in the current debate on selective visual attention concerns the brain sources of the top-down attentional signals to extrastriate and striate visual areas. Studies of brain-damaged patients, single-neuron recordings in primates and more recently blood-flow neuroimaging methods have identified a network of interconnected cortical and subcortical areas that play a key role in the control of selective visual attention. These areas include the dorsolateral prefrontal and posterior parietal cortex, the anterior cingulate gyrus, the pulvinar nucleus of the thalamus, and the superior colliculus (see Petersen and Posner, 2012; for a recent review). It has been proposed that in this circuitry, the prefrontal cortex would initiate and maintain the selective sensory bias in working memory, whereas the parietal cortex would direct and shift attention to specific objects and locations in space. In turn, this control network would enhance or suppress stimulus representations in the extrastriate visual areas according to current concern. Parietal and prefrontal cortex have anatomical and functional properties ideal for providing attentional templates. Both regions are extensively and reciprocally interconnected with virtually all visual cortical areas, and are therefore in a position to influence visual processing at multiple levels of the visual system. Neurons in the prefrontal and parietal cortex are capable of encoding the behavioral relevance or saliency of a visual stimulus. Furthermore, they display a pattern of activity that is well suited to form and maintain online a representation of an object or of a location for as long as that representation is relevant to behavior. In the past years, several functional neuroimaging studies in humans have shown frontal and parietal activations during visual attention tasks (see Kastner and Ungerleider, 2000; for a recent review). However, only recently top-down control signals for allocating attention have been distinguished from the modulatory effects that these signals have on the processing of incoming visual stimuli. For example, Hopfinger et al. (2000) asked which brain regions were activated in response to cues instructing shift or attention, and which were activated by the subsequent visual target presentation. A number of different visual areas were active; the surprising finding was that there was relatively little overlap between the two sets of visual responses. Importantly, posterior parietal and prefrontal areas were selectively engaged by attention-directing cues, thus suggesting that these two structures play a fundamental role in top-down attentional control. It should be noted, however, that the frontoparietal network is not exclusively related to visual attention, but may coincide or overlap with cortical regions involved in oculomotor processing (the FEF). This overlap supports the hypothesis that the neuronal signals used to direct attention correspond to the premotor signals that drive the eyes. One way to disentangle attentional and oculomotor processes would be an attentional task that does not require eye movements. In one study, for instance, subjects performed rapid attention shifting between the shape and color of stimuli presented at fixation, so that the need for eye movements eliminated (Le et al., 1998). Nevertheless, significant activations were observed in superior parietal lobule and other occipital visual areas, as well as the lateral cerebellum. Thus, it seems that at least some activity in the parietal and frontal cortex reflects attentional signals that are independent of eye movement. The frontoparietal circuit may therefore play a very general role in visual attention, governing the access of competing visual representations to higher brain centers and ultimately to perceptual consciousness.

Abstract

This article presents a summary of developments in the study of attitude formation and attitude change, two defining features of social psychology from its inception as an empirical science. Research on conceptualizations of change is discussed, as are variables implicated as attitude change agents. The interconnection of implicitly and explicitly measured attitudes is discussed, along with models devised to account for their mutual interplay.

Study of attitude formation and change is a central preoccupation of social psychology, and has been so from the beginning days of the discipline (Prislin and Crano, 2012). Research on attitudes provides an aperture into the conceptual system, supplies insights on complexities of human social behavior, and suggests how actions are affected by beliefs, and how beliefs affect actions. Advances in measurement, necessary for the scientific study of any phenomenon, were driven in the early days of attitude research by Louis Thurstone (1931), whose pioneering efforts conveyed the concept of attitude from speculation to operation. His insights were advanced and refined by Likert (1932) and Osgood et al. (1957), among others. Thurstone's view of attitudes as fundamentally evaluative was carried forward by his intellectual successors, and the field has largely followed this lead, though current views also include cognition and affect in definitions of the construct (e.g., "An attitude represents an evaluative integration of cognitions and affects experienced in relation to an object" (Crano and Prislin, 2006: p. 347).

Beyond measurement, programmatic experimentation on attitudes and attitude change grew largely from the efforts of Carl Hovland and his research group at Yale, where much of the foundational research on persuasion was undertaken (Hovland et al., 1953). Hovland's work affirmed Allport's (1935: p. 395) earlier appraisal that identified attitudes as social psychology's 'most distinctive and indispensable concept.' Although other actors have made their entrance on social psychology's stage since that time, attitude formation and change maintains the lead role.

Two fundamentally divergent views of the construct currently vie for adherents: the traditional position follows from and extends Thurstone's original evaluative emphasis, in which attitudes are conceptualized as enduring and stable structures that are stored in memory and vary in strength, which determines the attitude's stability and likelihood of affecting behavior (Fazio, 2007; Petty and Brinõl, 2009). The alternative (constructionist) position also hews to the evaluative nature of attitudes, but holds that attitudes are not stored in memory, but rather are constructed judgments influenced by the context in which they are assessed (Schwarz, 2007). Intermediate positions (e.g., Crano and Prislin, 2006) can accommodate either the traditional or constructivist views, and may provide a means of integrating both camps.

Attitude Formation and Change

Partly in response to Johnson and Eagly's (1990) stout critique of the field's failure to differentiate attitude formation from change, investigators have attended more closely to the distinction between these two cognitive processes. The best research on attitude change focuses on beliefs that are relevant to the individuals under study, whereas investigations of attitude formation are concerned with how attitudes develop in the first place.

Attitude Formation

Early research on attitude formation, initiated when learning-based models were in vogue, tested the possibility that attitudes could be established via classical or operant conditioning procedures. Both approaches were consistent with Thurstone's assumption that attitudes were fundamentally affective. Using classical conditioning processes, Staats and Staats (1958) found that consistent association of positively valenced words (e.g., gift, sacred, happy) with a national name (e.g., Dutch, Swedish) resulted in significantly more positive ratings of the national name than when the same name was associated with negatively valenced words (e.g., bitter, ugly, failure). This result held after subjects who claimed awareness of the study's purpose were removed from the analysis, though this procedure's utility has been challenged (Kattner et al., 2012; Stahl et al., 2009). Operant conditioning, too, can affect expressions of attitude. Insko (1965) verbally reinforced (good) university students for agreeing with positive or negative statements about a campus issue. This operant procedure clearly influenced responses. Furthermore, the effects persisted when students' attitudes were assessed 1 week later in a different context, by different researchers with the critical attitude items buried in a longer 'Local issues questionnaire.' Awareness of reinforcement contingencies is not a strong rival explanation of the persistent effects Insko reported.

More recent research on *evaluative conditioning* (EC) mirrors the findings of the classical conditioning school, but its proponents point to different underlying processes to explain conditioning effects. In the usual EC study, a picture of a neutral, unknown human face is presented repeatedly with a liked or disliked face, resulting in the originally neutral face

taking on the evaluative tone of the valenced one. The mere association of evaluative cues is sufficient for attitude formation. This position has many adherents (e.g., Forgas, 2008; Walther and Langer, 2010), but it is not without critics who maintain that cognitions (beliefs) and their associated evaluations, not mere affect, are the foundation of attitudes (Fishbein and Middlestadt, 1995). The weight of evidence favors the 'mere affective association' position, but whether EC can affect strong and highly vested attitudes remains at issue.

Contrary to results in classical conditioning, some have found that EC effects are strongest when respondents are *unaware* of the contingency between conditioned and unconditioned stimuli (De Houwer et al., 2001). However, controversy surrounding this position remains (Gawronski and Walther, 2012; Kattner et al., 2012). This issue is important as it bears on the effects of implicit attitudes on actions and explicit beliefs (Greenwald et al., 1998), the focus of considerable interest today. What appear noncontroversial are the distinctions between classical and evaluative conditioning. The latter, for example, apparently is not dependent on temporal contiguity between the unconditioned and conditioned stimuli. Furthermore, linkages formed by evaluative conditioning seem considerably more resistant to extinction than classically conditioned associations (Walther and Langer, 2008). These differences suggest the more widespread use of evaluative conditioning in field settings, especially in applications involving attitude formation, that is, on issues on which no firmly established belief exists.

Attitude Change

Study of attitude change logically presupposes preexisting attitudes, which may vary in terms of strength and centrality. An essential task of the attitude change researcher is to understand the factors that render an individual more or less susceptible to persuasion. A standard assumption in almost all of the foundational theories is that people strive to attain and maintain valid beliefs. Consistent with this assumption is the expectation that the more self-relevant the attitude, the more difficult it will be to change. These assumptions have formed the basis of considerable research in traditional studies of attitude change.

Hovland's Base Model

The formative model of attitude change was developed by Hovland et al. (1953), who made a critical but often overlooked distinction between attitudes and opinions. Attitudes were thought to involve nonverbalizable, often unconscious implicit approach–avoidance tendencies; opinions, on the other hand, were the verbal answers that one produced overtly or covertly to questions regarding the evaluation of a person or object. The technology of Hovland's time precluded study of implicit cognitive–behavioral responses (attitudes), and so by his definition, 'attitude change' research actually focused on opinions (explicit evaluative judgments), expressed and assessed on standard attitude measures. (To maintain consistency with contemporary usage, we will use the terms interchangeably.) Hovland's stress on the implicit nature of attitudes foreshadowed current considerations of implicit and explicit attitudes, though his theory of communication and persuasion implies strong interrelatedness between them; that is, that explicit opinions and implicit attitudes were strongly associated, and that large discrepancies, resulting in unpleasant cognitive disequilibrium or imbalance, would create the conditions for change.

Message Design, Elaboration, and Counterargumentation

Hovland et al. (1953) assumed that if a persuasive message were noticed and relevant to the individual, it would be considered carefully (i.e., elaborated). This elaboration process, which involved careful consideration of the persuader's arguments, also was accompanied by a defensive response called counterargumentation, which protected established beliefs. Thus, developing methods to overcome counterargumentation was the central goal of persuasion in Hovland's scheme. To realize this objective, it was necessary that a persuasive message raises a question in the receiver's mind about the legitimacy or validity of an established attitude. Furthermore, to succeed, the communication had to provide an answer to the question that suggested the appropriate response. Hovland's model was developed when social psychology was strongly influenced by learning theory. Consistent with this then-popular approach, it was assumed that opinions were learned and that new learning was needed to overlay old knowledge in producing change. Attitude change was viewed as a function of message learning, and so factors thought to reinforce learning and acceptance of the persuader's position, thus resulting in 'attitude change,' were the fundamental variables of study. Many variables have been shown to influence the attitude change process in ways predicted by Hovland and associates, even though the underlying link between message learning and attitude change often was not evident, even in research that succeeded in changing attitudes. An abbreviated sampling of some of the most established persuasion variables is presented on the following pages.

Source

Features of the source of a persuasive communication have proven important to the success or failure of an attempt at influence. In Hovland's learning-based model, being in agreement (and identified) with a respected message source was reinforcing, thus prompting acceptance of the position advanced. Source credibility, as this variable is commonly termed, was defined as a function of the source's expertise – its capacity to provide valid information – and the source's trustworthiness – its willingness to provide honest information independent of self-interest. Sources of high levels of expertise and trustworthiness induce considerably more change than those that do not possess these features. It should be noted, however, that source credibility effects often prove ephemeral, an aspect of the persuasion equation noted even in the earliest studies of this variable (Hovland and Weiss, 1951).

Minority versus Majority Sources of Influence

An exciting extension of research on source credibility developed from Moscovici's (1980) seminal work on the influence of minority groups on the majority. After Moscovici,

considerable research was conducted to study the different effects of majority and minority message sources on persuasion. The literature indicates that both the minority and the majority can induce influence, but the cognitive processes underlying change in response to one the other of these groups are different and produce differences in the longevity of the altered beliefs (Crano, 2012; Crano and Alvaro, 1998). Attitude change usually occurs rapidly in response to a majority-sourced communication, but such change typically does not persist because it is based, theoretically, on threat and social pressure, and not on careful message elaboration.

Conversely, minorities rarely evoke immediate change; rather, if the minority is a part of the majority (i.e., if it is an in-group minority), and it is active – that is, willing to take the risk involved in confronting majority group members – then the majority may change attitudes on issues related, but not identical to the focus of the minority's communication. Furthermore, if this indirect change of majority members' attitudes is sufficiently large, a delayed change may occur on the attitude that was the original focus of the minority's persuasive communication. Crano and Alvaro (1998) and Martin and Hewstone (2008) have suggested theoretical models that account for this unusual but often observed pattern of results.

Fear Arousal

If positive reinforcement of a behavior results in a higher likelihood of the behavior's being repeated, then the reinforcement experienced by avoiding a negative behavioral outcome should induce avoidance of the behavior. This logic is the basis of considerable research on emotional or fear-arousing communications, which have an enormous appeal in applied research contexts (e.g., alcohol, tobacco, or drug prevention, lifestyle changes). Unfortunately, many such applications have been mounted by change agents who appear to misunderstand the principles involved in their use. It is critical to understand the way reinforcement operates when using fear arousing communications to promote attitude change. Thus, to threaten an individual with dire consequences for, say, using methamphetamines would not be expected to succeed if the target of the message is already concerned about the practice (e.g., is a user of the substance). Avoiding a negative outcome is reinforcing, but if the targeted behavior is ongoing, the fear-arousing message, not the proscribed behavior, is the likely candidate for avoidance (Witte, 1992). This type of communication can be effective if it is not overdone with threats the target finds unrealistic (Skenderian et al., 2008) or punishing (i.e., threatens negative outcomes for ongoing behavior), and the message is presented by a credible source who offers a way of effectively avoiding the threatened consequences of the behavior. Without satisfying these requirements, fear-arousing messages are likely to produce no change or, in the worst case scenarios, iatrogenic effects as a result of message rejection, possibly brought about by source derogation or psychological reactance (Brehm, 2000).

Distraction

Counterarguing draws upon scarce cognitive resources. Thus, it is not likely to be engaged in contexts involving issues that are unimportant to the receiver. This is one of many reasons why it is easier to persuade receivers to accept a message on topics on which they are not vested. Contexts that occupy cognitive resources also are expected to disrupt counterargumentation, and thus, increase the likelihood of successful persuasion. Petty et al. (1976) showed that distraction inhibited the dominant cognitive response to a persuasive communication. Thus, distraction enhanced attitude change when the dominant response was negative, as often is found with illogical and poorly argued communications. However, distraction interfered with the positive cognitive responses that typically follow from elaboration of logical and strongly argued communications. In this case, distraction inhibited attitude change. This research laid the groundwork for Petty and Cacioppo's (1986) elaboration likelihood model of attitude change (*see* Persuasion Theories).

Overload

Research on 'cognitive busyness' suggests that individuals working under cognitive load are less able to counterargue, and thus, are more susceptible to persuasive communications (Gilbert et al., 1988). This hypothesis can be augmented by considering message quality. As in research on distraction and persuasion, it is likely that cognitive overload enhances the relative persuasive power of weak messages by attenuating negative cognitive responses, but weakens the persuasiveness of strong and logical messages by moderating positive responses, which lead to message acceptance. If nothing else, research on distraction and cognitive load counsel against simple univariate explanations of complex human behavior, a theme that is replicated throughout the literature on persuasion.

Mood

Early research on the effects of mood on susceptibility to attitude change suggested that positive moods rendered receivers unlikely to elaborate persuasive communications carefully. Those in a positive mood state seemed susceptible to attitude change regardless of the quality of the persuasive communication. Message quality was thought to be a more important factor for those in neutral or negative mood states (Mackie and Worth, 1989). Findings based on Wegener et al. (1995) hedonic contingency hypothesis, however, suggests a somewhat different interpretation. In Wegener and associates' view, a happy mood state enhances message processing if the communication does not threaten to ruin the happy mood, or if the message is uplifting. However, if the message is depressing, happy people are less likely to process it. Happy people, it seems, are intent on remaining so, and thus are likely to seek out information that supports this goal. Unhappy people, on the other hand, seem motivated to alleviate their negative state, and thus will process information that might result in a happy ending. This possibility was supported in Hullett's (2005: p. 423) *meta*-analysis of research on the mood–persuasion association, which found that "participants' processing of messages seemed to be motivated toward attaining or maintaining positive moods."

This emphasis on the hedonic consequences of a persuasive communication anticipated research that indicated that

positively framed communications were more persuasive for participants in positive than negative mood states, especially when the communication was strong and logical. For those in negative mood states, the hedonistic consequences of message framing and quality were less important, as most messages would be likely to improve mood, and hence were not elaborated carefully (Wegener et al., 1995).

Misdirection

One would not expect an individual to counterargue a persuasive communication if it was addressed to another person. This expectation was confirmed by Walster and Festinger (1962), who found that an 'overheard' communication induced considerably more attitude change than an identical message targeted to the receiver. This misdirection effect, as it has come to be called, is based on the logic of counterargumentation Hovland et al. (1953) advanced, and represents an interesting technique used to circumvent resistance. It has been used successfully in many persuasion contexts. For instance, apparently misdirected messages were shown to be strongly persuasive in antidrug research involving young adolescents, a group that usually is resistant to such communications. The results of an experiment by Crano et al. (2007), for example, indicated that youth who had received a communication apparently directed toward their parents were significantly more affected by it than were adolescents to whom the communication was addressed directly. The communications themselves differed by only a few words in the introduction, which specified the apparent audience of the message, parents or their children.

Ambivalence

To this point, attitudes have been discussed as unidimensional like–dislike, evaluative constructs. Research on attitude ambivalence suggests that this conceptualization may be incomplete. Attitudes may possess positive and negative evaluations simultaneously, thus generating the experience of ambivalence (Newby-Clark et al., 2002). Distinguishing ambivalent from neutral attitudes has attracted considerable research attention (Conner and Armitage, 2008), suggesting the importance of the distinction. High levels of ambivalence are associated with weaker attitude–behavior relations, and less resistance to counterattitudinal communications (Conner and Armitage, 2008). The development of ambivalent attitudes, as distinct from neutral attitudes, is viewed by some as the result of contradictory values (Feather, 2004), which suggests why contradictory evaluations of the same object may be expressed by the same individual at different times, depending on the social context in which the evaluation is elicited. This is not to suggest that attitudinal ambivalence is a positive or sought-after state. It should be understood that the motivation to maintain consistency among cognitions is strong (Gawronski and Strack, 2012), and research has highlighted the ways in which explicit attitudes affect implicit ones, and vice versa, to establish the preferred and probably normative state of cognitive balance (Peters and Gawronski, 2011). As will be discussed, both poles of an ambivalent attitude may affect the other; the general dynamic of the cognitive system, however, appears to press for consistency among beliefs.

Implicit and Explicit Attitude Measurement and Change

Feather's (2004) description of ambivalent attitudes as reflecting the simultaneous possession of positive and negative attitudes toward the same object of judgment provides the basis for a deeper understanding of implicitly and explicitly measured attitudes. Implicit, often nonverbalizable attitudes are thought to develop slowly, the result of a consistent pairing of an unconditioned with a conditioned stimulus. They are slower to change than explicit attitudes, which are formed more rapidly as a function of "evaluative judgments that are based on syllogistic inferences" (Gawronski and Bodenhausen, 2006: p. 694). Research by Rydell et al. (2006) anticipated this view by showing that implicitly and explicitly measured attitudes were formed in different ways, and, importantly, were susceptible to different persuasive processes.

The standard models of attitude change (e.g., Petty and Cacioppo, 1986; Chaiken, 1980) were developed before the technology to assess attitudes implicitly was commonly available, and hence were focused on change of explicit attitudes. In the meantime, with technological advances, new models of attitude structure and change were developed to account for the interaction of implicit and explicit beliefs. Gawronski and Bodenhausen's (2006: p. 693) associative–propositional evaluation (APE) model, for example, "specifies causes of implicit and explicit attitude change and how changes in one kind of evaluation may or may not be associated with changes in the other." This is not to suggest that the 'standard' models cannot also account for the newly available – if not newly theorized – features of attitudes; the possible conflict of implicit and explicit attitudes can be seen as compatible with attitude models developed before implicit attitudes even could be assessed. Petty and Briñol (2009), for example, described one such integration in their metacognitive model (MCM) of attitude structure. In the MCM, evaluative associations can be formed in many ways, and to the extent that they are implicit or below awareness, are treated as valid. If the holder of an implicit attitude is unaware of its existence, it is not subject to dispute or direct falsification. Incongruity between attitudes measured with implicit or explicit measures can induce evaluative change on either the implicit or the explicit belief. These changes are predictable, and in part a function of the circumstances under which the incongruity was induced. A strong persuasive attack on an explicit attitude, for example, would be expected to affect the explicit attitude; if successful (i.e., if the explicit measure indicated attitude change in the advocated direction), movement on the implicit attitude might result as well, likely as a function of the preference for cognitive consistency noted earlier. An intriguing prediction from the MCM is that the more extreme the discrepancy between explicit and implicit attitudes, the greater will be the accommodation of one or the other when pressure for congruity motivates attitude change. Supportive evidence for this expectation is found in the literature on minority-induced indirect attitude change, where minorities often induce the majority to change on issues related, but not identical to the thrust of the persuasive attack (Moscovici, 1980). Research has shown that

extremity of indirect change is associated with likelihood of delayed direct change, as hypothesized in Crano and Alvaro's (1998) Context/Comparison Model of minority influence, Petty and Brinõl's (2009) MCM, and confirmed by Crano and Chen's (1998) empirical research.

Some Concluding Thoughts

Research on attitudes has witnessed enormous progress over the years, even though many of the issue and constructs of current interest have been contemplated and contested since the earliest days of research on persuasion. The march of progress in measurement, along with the accumulation of empirical substantive knowledge resulting from 60 years of intense research interest, has created a literature that is as rich as it is generative. The theoretical debates that have occurred over the years often ended in a draw, in which both sides of the issue owned part, or all of the truth, which they approached in somewhat different ways and from somewhat different points of view. A similar integration of current models also will occur, hopefully before too much more time has passed. The established models of persuasion have focused primarily on the formation and change of explicit attitudes, and often presuppose stored representations of person or object evaluations. These representations can have powerful effects on judgments and behavior. However, as shown, they do not preclude the possibility that implicit attitudes also can affect explicit beliefs and behaviors. The same can be said of the more recent models, which have emphasized the importance of implicitly identified attitudes. From the start, the more recent models of attitude formation and change had to come to grips with implicit associations, which often seemed to operate below the conscious awareness of their holders. These models, however, also had to create mechanisms allowing for the interaction of explicitly and implicitly measured attitudes. Models of persuasion that accommodate implicit and explicit attitudes, and that account for their mutual interplay in light of our clear preference for consistency among beliefs, represent the next peak in the topography of attitude research (Prislin and Crano, 2008).

Attitude: History of Concept

Christian Fleck, University of Graz, Graz, Austria

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The concept 'attitude' became used widely in several social science disciplines to indicate a relatively stable evaluative stance of a person toward any object. Originally from the language of painting and sculpture, the term became used to designate an inner preparedness of some stability. Rivaling with competitors in the public space around the turn of the twentieth century such as instinct, imitation, habit, etc., attitude outperformed others primarily because Thurstone suggested a measurement technique which became within a very short period of time the standard technique to gauge opinions. A set of items which could be scaled between opposing extremes is then an attitude variable and the single items are attitudes.

'Attitude' entered the vocabulary of the social and behavioral sciences early in the twentieth century after the term had traveled for a while in other corners of language uses. A look at the prehistory of the concept reveals some of the advantages and problems it later experienced. Unlike many other social science concepts, the word 'attitude' existed in more than one Indo-European language in the same form before the social sciences captured it for their own use: *Attitudine* in Italian, *attitude* first in French and then in English. The word goes back to the medieval Latin *aptitude* and the classical *aptus* (*Oxford English Dictionary*; Fleming, 1967: 292). Before becoming a social science concept, 'attitude' was used in painting and in particular in sculpture to describe a bodily pose of an individual who presents him/herself: as in present day usage 'to strike an attitude.' Here it is less clear whether the term is directed more to the person's preparedness and execution or the position reached finally. By referring to something located inside a human and not easily observable, 'attitude' encompassed something which became attractive for social scientists.

According to Fleming (1967: 293–297) Charles Darwin made use of attitude for the first time conceptually. In *Expression of the Emotions in Man and Animals* (1872) he discusses the, for him surprising, fact that particular strong emotions are accompanied by gestures, bodily postures expressing the emotion where a vis-à-vis can understand the emotion of the other by reading the body gestures. Attitudes are, for Darwin in this book, strong motor expressions of a particular emotion. Since Darwin was read widely one can presume that his repeated use of the term attitude functioned as the way in which the term entered the language of the social sciences.

Fleming (1967) discusses a second way attitude could have become the concept it was from the 1920s onward. Back then psychologists worldwide looked at Germany as the most mature representation of the discipline, and since the majority of professional psychologists and other social and behavioral scientists of that time not only read German but often studied in Germany, it could have been the case that the translation of the German *Einstellung* as attitude was the way attitude became the concept we know today. In this case, it would have been the Würzburg School of *Denkpsychologie* – Oswald Külpe, Narziß Ach, and their pupils – who developed in their experiments their own conceptual language. Someone has to solve a task (*Aufgabe*) and the experimental psychologists interviewed the participants afterward about their inner reasoning, their thinking while executing the task, inviting the selected participants to execute introspection, then regarded as the bridge into the brain, so to speak. German *Denkpsychologen* used several composite words to describe what happened in the person before executing an action. One single word expression for this phenomenon inside an actor was *Einstellung* and when E.B. Titchener worked on a translation of works from the Würzburg School he had chosen attitude for it.

Furthermore we need to recognize that attitude had to fight against the prominent rivals occupying the intellectual space of the late nineteenth- and early twentieth-century discourses. Imitation following Gabriel Tarde and instinct with no similar prominent coiner populated the textbooks of social psychology and sociology of the early years of the twentieth century together with habit as more or less synonymous expressions. But also belief, opinion, wish, idea, mental and emotional 'states,' etc., populated the universe from which social scientists took out what pleased them to speak about unobservable moves in people's inner life. Even if one used 'attitude,' he was free to define it as it pleased the author. For instance, Franklin H. Giddings from Columbia University in his textbook *The Principles of Sociology: An Analysis of the Phenomena of Association and of Social Organization* (1896) describes the phenomenon of communication as a form of association: "The expression of conscious states by means of attitude, muscular movement, and utterance is a language common to animals and men" (Giddings, [1896] 1916: 108).

More broadly and with higher impact is what William I. Thomas from the University of Chicago contributed to the establishment of attitude as a social science concept. He not only studied in Germany but read widely according to his biographers-interpreters and he was teaching a course on 'social attitudes' from 1900 onward (Fleming, 1967: 322). Fleming identified casual usage of attitude in some of the early writings of Thomas but there is widespread consensus in the small literature on the conceptual history of attitude that *The Polish Peasant in America* (1918) was the birthplace of the sociological and social psychological concept of attitudes, initially mostly used with the prefix social. Both Thomas's teaching and the book functioned as media to make attitude, the concept it remains since then.

Thomas positioned attitude explanatorily in a prominent environment (and his coauthor Florian Znaniecki; but there is wide agreement that the famous Methodological Note – of 86 pages – was written by Thomas alone). He claims that there are two "fundamental practical problems … which have constituted the center of attention of reflective social practice in all times" (Thomas and Znaniecki, [1918]1927: 20). On the one hand the 'dependence of the individual upon social organization and culture' and on the other hand the 'dependence of social organization and culture on the individual' (Thomas and Znaniecki, [1918]1927). According to Thomas, the first problem could be reformulated as the question "How should we produce the desirable mental and moral characteristics in the individuals constituting the social group?" whereas the second problem "How should we produce the desirable type of social organization and culture?" In a footnote, he even adds that the two practical turns might strengthen each other in succinct steps of doing. For these two sides – the objective and the subjective – Thomas then proposed two concepts: value and attitude.

> By a social value we understand any datum having an empirical content accessible to the members of some social group and a meaning with regard to which it is or may be an object of activity.
>
> Thomas and Znaniecki, [1918]1927: 21

And he adds after this well-done definition a list of illustrative cases of values: "Thus, a foodstuff, an instrument, a coin, a piece of poetry, a university, a myth, a scientific theory, are social values" because individuals could act according to them transforming any natural object into a meaningful subject of activities.

Moving to the other concept Thomas defines attitude as "a process of individual consciousness which determines real or possible activity of the individual in the social world" (Thomas and Znaniecki, [1918]1927: 22). Less well developed than the other definition, the list of illustrations makes clear what Thomas had in mind: "Thus, hunger that compels the consumption of foodstuff; the workman's decision to use the tool," etc. The list of conceptual correspondences is revealing: Compel, decision, tendency, feeling, expression, sympathy and admiration, needs, fear, devotion, creating, understanding, and the ways of thinking – 'all these are attitudes' (Thomas and Znaniecki, [1918]1927).

Thomas goes even a step further and assigns social psychology to take care of attitudes because they are the subjective side of the phenomenon, entrusts sociology to concentrate on the objective axis, and investigates values. The Methodological Note did not remain the *locus classicus* of the early understanding of attitude because Thomas reworked his conceptual scheme continuously. He puts, figuratively speaking, below attitudes and values wishes – most probably his adoption of Freud's *Trieb* (alternatively translated into English as drive or instinct) – and proposed that the spectrum of wishes could be classified into his famous 'four whishes': desires for new experience, security, response, and recognition. These forcing powers then mold both the selection of values and the formation of attitudes in a particular 'situation' which is accompanied by the 'definition of the situation' either by an individual or offered by social groups or culture as such.

The major drive behind Thomas and others concerned with the concept attitude should be seen in the light of the scholarly discourses in the first decades of the twentieth century. The strong performance of behaviorism prompted authors to propose means to describe observable processes of behavior by abstaining from any introspection as a valid tool for research on humans' actions. What followed was the recession of the tradition of *Denkpsychologie* and the encapsulation of Freud's and others' depth psychology from academic discourses. The tradition to which Thomas contributed switches to a 'behavioralistic' language in presenting their insights.

Robert E. Park and Ernest W. Burgess's *Introduction to the Science of Sociology* ([1921]1942), the 'green bible' of the early Chicago School, contains under the chapter heading Social Forces several concepts aside from attitude (interests, social pressure, idea-forces, sentiments, wishes). The chapter's introduction, the selected exemplary text, and the recommendations for further readings show strong affinities toward psychoanalysis and committed to Thomas's four wishes but the explanation of what an attitude is remains highly elusive. Instead of defining attitude, the authors offer what attitudes are not:

> They are not instincts, nor appetites, nor habits, for these refer to specific tendencies to act that condition attitudes but do not define them. Attitudes are not the same as emotions or sentiments although attitudes always are emotionally toned and frequently supported by sentiments. Opinions are not attitudes. An opinion is rather a statement made to justify and make intelligible an existing attitude or bias. A wish is an inherited tendency or instinct which has been fixed by attention directed to objects, persons, or patterns of behavior, all of which then assume the character of values. An attitude is the tendency of the person to react positively or negatively to the total situation. Accordingly, attitudes may be defined as the mobilization of the will of the person.
>
> Park and Burgess, 1942: 438

There is some family resemblance to what later analytic philosophers did with ambiguous expressions by focusing on the use of them by different speakers, but Park and Burgess do not go explicitly into this direction, very much to their and attitude's disadvantage. Just as one illustration of what Park and Burgess did have in mind one could see from the list of topics suggested for written examinations: "Typical Attitudes: Familism, Individualism, 'Oppressed Nationality Psychosis,' Race Prejudice" or from the list of questions for discussion: "How far would you say that the attitude may be described as an organization of the wishes?" (Park and Burgess, 1942: 502–503).

Attitude entered center stage only when the statistical versatile psychologist L.L. Thurstone applied his measurement competencies to attitudes too. In 1928 he published a programmatic statement 'Attitudes Can Be Measured' which paved the way for the, until then, very vague concept. Similar to the concept intelligence, which became usable via measuring it, also attitude made its success along the road of operationalism. Thurstone borrowed from psychophysical experiments the idea of the 'just noticeable difference' to propose a continuum with opposite extremes and a set of items in between. He illustrated

his proposal by referring to an attitude variable militarism-pacifism, with a neutral zone in the middle. The 10 items running from one extreme to the other have been selected in a multilevel process. From a first long list of brief statements from anywhere (questionnaire, press, publications, letter, etc.) those items have been removed which did not allow to accept or reject them. The reduced list was then given to a group of several hundred 'judges or readers' asking them to order the items "in eleven piles ranging from opinions most strongly affirmative to those most strongly negative" (Thurstone, 1928: 545). Further refinements which became standard afterward generated a much shorter list of scaled attitude items where every single item stands for an attitude related to the topic with its opposite extremes.

Thurstone did not solve a single conceptual ambiguity but suggested a solution in the way to transform an undecidable conceptual problem into an empirical measurable analysis. The next decades demonstrated the attractiveness of this proposal (an early affirmative review of the field of attitude research is Gordon W. Allport (1935)). In particular, in psychology and social psychology measuring attitudes, forming and changing attitudes, and investigating the correlation between attitudes and behavior are still around. The techniques of scaling have been applied to other measurable dispositions and routinization sidestepped any debate about explanatory power of the concept attitude.

Abstract

The term *attitude* refers to a predisposition to evaluate some object in a favorable or unfavorable manner. This predisposition cannot be directly observed and is inferred from individuals' responses to the attitude object. Different measurement strategies draw on different types of responses. They include answers to direct questions; the observation of overt behaviors; and responses that may be outside of the individual's awareness, such as minute facial expressions and response time differences in the range of milliseconds. The advantages and disadvantages of different measurement strategies and their conceptual implications are discussed.

The term *attitude* refers to a hypothetical construct, namely a predisposition to evaluate some object in a favorable or unfavorable manner. This predisposition cannot be directly observed and is inferred from individuals' responses to the attitude object, which can run from overt behavior (such as approaching or avoiding the object) and explicit verbal statements to covert responses, which may be outside of the individual's awareness (such as minute facial expressions or small differences in the speed of a response). This article reviews diverse measurement procedures that draw on these different manifestations of attitudes (for a history, see Oskamp, 1991).

Explicit Self-Reports

Most attitude researchers rely on respondents' answers to questions, such as "Do you approve or disapprove of how President Obama is handling his job?" Direct questions are the most feasible procedure for assessing the attitudes of the population at large, e.g., in representative sample surveys. However, self-reports of attitudes are highly context dependent and minor changes in question wording, question format, and question order can profoundly alter the obtained results. This section addresses the underlying processes and their implications for the measurement and conceptualization of attitudes.

The Question Answering Process

To answer an attitude question, respondents need to (1) understand the meaning of the question; (2) retrieve relevant information from memory to; and (3) form an attitude judgment. In most cases, they also need to (4) map their judgment onto the response alternatives provided by the researcher; and they (5) may want to edit their response before they report it, due to reasons of social desirability and self-presentation. Respondents' performance at each of these steps is highly context dependent (for comprehensive treatments see Sudman et al., 1996; Tourangeau et al., 2000). The cognitive and communicative processes involved in these tasks are reviewed in *Questionnaires: Cognitive Approaches*, and this material applies directly to attitude questions. The following discussion is restricted to specific aspects of the judgment stage and the use of different response formats.

Evaluating Attitude Objects

Once respondents determined what the question refers to, they need to recall relevant information from memory. In some cases, they may have direct access to a previously formed relevant judgment that they can offer as an answer. In most cases, however, they will not find an appropriate answer readily stored in memory and will need to compute a judgment on the spot. To do so, they need to form a mental representation of the attitude object and of a standard, against which the object is evaluated. The resulting judgment depends on which information happens to come to mind at that point in time and on how this information is used.

As a large body of research demonstrated, individuals rarely retrieve all information that may bear on an attitude object but truncate the search process as soon as enough information has been retrieved to form a judgment with sufficient subjective certainty. Hence, the judgment depends on the first few pieces of information that come to mind. Whereas some information may always come to mind when the person thinks of this object (and is therefore called *chronically accessible*), other information may be only *temporarily accessible*, for example, because it has been brought to mind by preceding questions. Changes in what is temporarily accessible are at the heart of many context effects in attitude measurement, whereas chronically accessible information contributes some stability to attitude judgments.

How accessible information influences the attitude judgment depends on how it is used (Bless and Schwarz, 2010). Information that is included in the mental representation formed of the attitude object results in *assimilation effects*, i.e., the judgment becomes more positive (negative) when information with positive (negative) implications comes to mind. In contrast, information that is used in forming a mental representation of the standard against which the attitude object is evaluated results in *contrast effects*. In this case, the judgment becomes more negative (positive) when information with positive (negative) implications comes to mind and is used as a positive (negative) standard of comparison. Suppose, for example, that a preceding question brings a politician to mind who was involved in a scandal (say, Richard Nixon). When a subsequent question pertains to the trustworthiness of American politicians in general (a superordinate category), Richard Nixon is likely to be included in the representation formed of 'politicians' as a group, resulting

 http://dx.doi.org/10.1016/B978-0-08-097086-8.24006-3

in judgments of decreased trustworthiness (an *assimilation effect*). Suppose, however, that the question pertains to the trustworthiness of Barack Obama (a lateral category), rather than to politicians in general. In this case, Richard Nixon cannot be included in the representation formed of the attitude object 'Obama'; instead, he is likely to serve as a (rather negative) standard of comparison, relative to which Barack Obama will be evaluated as more trustworthy than would otherwise be the case (a *contrast effect*). As this example illustrates, the same context question can have opposite effects on superficially similar subsequent questions, resulting in many apparent inconsistencies. In the present case, a researcher might conclude that political scandals decrease trust in politicians when judgments of the group are used as the dependent variable, but increase trust in politicians when judgments of individual politicians are used as the dependent variable.

Whether a given piece of information is used in constructing a representation of the attitude object (resulting in assimilation effects), or of a standard of comparison (resulting in contrast effects), depends on a host of different variables. Bless and Schwarz (2010) review these variables and present a theoretical model that predicts the direction, size, and generalization of context effects in attitude measurement.

Some Attitude Scale Formats

Textbooks consistently advise researchers to use multiitem scales. However, the classic examples of multiitem attitude scales – namely, *Thurstone scales, Guttman scales*, and *Likert scales* (see Eagly and Chaiken 1993: Chapter 2) – are rarely used in practice, primarily because they require extensive, topic-specific development work. An exception is Osgood and colleagues' *Semantic Differential Scale* (see Eagly and Chaiken, 1993: Chapter 2), which is a ready-to-use scale that can be applied to any topic, making it considerably more popular. Respondents are asked to rate the attitude object (e.g., 'welfare') on a set of seven-point bipolar adjective scales. The adjectives used as endpoint labels reflect three general factors, namely evaluation (e.g., good–bad; pleasant–unpleasant), potency (e.g., strong–weak; small–large), and activity (e.g., active–passive; fast–slow). Of these factors, evaluation is considered the primary indicator of respondents' attitude toward the object, as reflected in the objects' (relatively global) connotative meaning.

In most studies respondents' attitudes are assessed by only one or two questions, presented either with multiple-choice response alternatives or a rating scale. When the question offers several distinct opinions in a *multiple-choice format*, it is important to ensure that the set of response alternatives offered covers the whole range of plausible positions. Any option omitted from the set is unlikely to be reported at all, even when respondents are offered a general 'other' response option, which they rarely endorse. Similarly, few respondents report not having an opinion on an issue when this option is not explicitly provided – yet, they may be happy to report so when 'do not know' is offered as an alternative (see Sudman et al., 1996: Chapter 3).

When *rating scales* are used, respondents are presented with a numerical scale with verbally labeled endpoints (e.g., -3 = 'strongly disagree,' $+3$ = 'strongly agree') and asked to check the number that best represents their opinion. Alternatively, each point of the rating scale may be labeled, a format that is common in telephone interviews. In general, the retest reliability of fully labeled scales is somewhat higher than that of partially labeled scales and retest reliability decreases as the number of scale points increases beyond seven, reflecting the difficulty of making many fine-grained distinctions. What is often overlooked is that the numeric values of the scale may influence respondents' substantive interpretation of the question. For example, when asked to report how highly they think of a politician along a scale from 'not so highly' to 'very highly,' respondents need to determine if 'not so highly' pertains to the absence of positive thoughts or to the presence of negative thoughts. When the numeric values run from 0 to 10, respondents interpret 0 = 'not so highly' as reflecting the absence of positive thoughts; but when the scale runs from -5 to $+5$, they interpret -5 = 'not so highly' as pertaining to the presence of negative thoughts. In general, scales that range from negative to positive numbers suggest that the researcher has a bipolar dimension in mind, implying that one endpoint label refers to the *opposite* of the other; in contrast, scales that present only positive numbers suggest a unipolar dimension, implying that different scale values pertain to different degrees of the *same* attribute. Such shifts in question meaning result in markedly different responses (see Schwarz, 1994 for what respondents learn from scales and other formal characteristics of questionnaires).

Implications

From a measurement perspective, the reviewed influences highlight the need to pay close attention to how respondents make sense of the question asked. Suitable methods can be employed at the questionnaire development stage; they are discussed in *Questionnaires: Cognitive Approaches*. From a theoretical perspective, the emergence of context effects poses important challenges for the traditional conceptualization of attitudes as enduring dispositions. One response to this challenge holds that context effects may only emerge when respondents have not thought much about an issue, but not when they have formed strong, or crystallized, attitudes. Empirically, this *attitude strength* hypothesis has received little support; although strong attitudes are more resistant to explicit persuasion attempts, they are not more resistant to contextual influences in the question answering process (for a review, see Krosnick and Abelson, 1992). A second response emphasized that explicit self-reports of attitudes are subject to self-presentation concerns – respondents may know their true and enduring attitude but may be unwilling to report it, tailoring the answer instead to what seems reasonable in the context of the interview. This concern motivated attempts to reduce socially desirable responding.

Reducing Socially Desirable Responding

Some procedures aim to reduce socially desirable responding by making it easier to report undesirable positions (for a review, see Tourangeau et al., 2000). They range from simple assurances of anonymity and confidentiality to complex randomized response techniques. In the latter case, respondents are presented with two different questions, an innocuous one and a socially sensitive one, and a draw a card that determines which one they are to answer. Given properly worded

response alternatives, the interviewer remains unaware to which question the answer pertains, thus ensuring the highest possible level of confidentiality. Other procedures create conditions that increase the perceived cost of socially desirable responding. For example, a 'bogus pipeline' technique involves convincing participants that the researcher can discern their true attitude independent of what they say, thus making lying an embarrassment. Empirically, these various techniques have been found to increase the frequency of socially undesirable answers. However, they do not affect the emergence of most context effects, suggesting that the most context effects are driven by processes of evaluative judgment rather than by concerns about one's public appearance.

Note, however, that all attempts to reduce socially desirable answers to explicit attitude questions rest on the assumption that respondents know their attitude and merely hesitate to report it to others. Wondering whether deception and self-presentation may also be directed toward the self, some researchers began to develop *implicit attitude measures* that attempt to assess attitudes of which people may not even be aware or may not want to admit to themselves.

Implicit Attitude Measures

Implicit measures are based on the assumption that attitudes exert a systematic influence on people's performance on a variety of tasks and that the size of this influence can serve as an index of the underlying attitude (for reviews of different measures and their theoretical rationales see the contributions in Wittenbrink and Schwarz, 2007). This measurement logic requires clear bridging rules that specify the theoretical and empirical relationship between the attitude and the measurement task. Not surprisingly, these bridging rules have varied widely over the history of attitude research. From the early use of projective tests to the current use of response latency measures, the history of indirect measures mirrors historical shifts in the conceptualization of attitudes and their underlying processes (see Vargas et al., 2007).

Response Time Measures

Response time measures of implicit attitudes take advantage of one of two regularities. First, preceding exposure to a stimulus facilitates subsequent responses to related stimuli. For example, after seeing the word 'doctor,' we are faster at recognizing or pronouncing the word 'nurse.' This *response facilitation effect* can be used to gauge which concepts are, or are not, closely associated in a person's mind. Second, a stimulus is responded to more slowly when it contains multiple features that give rise to competing responses. For example, it takes longer to name the color in which a word is printed when the meaning of the word and the print color diverge, e.g., when the word 'green' is printed in blue ink. This *response competition effect* can be used to gauge which responses are compatible or incompatible in a person's mind.

Response Facilitation Measures

One strategy involves the presentation of target words with evaluative meaning (e.g., lazy, smart) and measures how fast respondents can identify the word. Speed of identification can be assessed by asking respondents to pronounce the word as fast as possible or to decide quickly whether a letter string is a word or a nonword. Of interest is whether a preceding stimulus (called a 'prime') that represents the attitude object of interests affects the speed with which different target words can be identified. For example, a faster response to the word 'lazy' after exposure to the word 'black' than after exposure to the word 'white' is indicative of negative racial stereotypes about Blacks, as first observed by Gaertner and colleagues in the early 1980s. The response time patterns generated by such *concept priming procedures* can be brought to bear on three questions: First, does exposure to the attitude object activate associated beliefs? Any concept that is processed faster after exposure to the attitude object is associated with it, even though the person may not be aware of it. Second, is the activation of beliefs evaluatively biased? For example, are negative attributes identified more quickly than positive ones? Third, does exposure to the attitude object activate general evaluative associations (e.g., good, bad)?

A related strategy focuses solely on evaluative associations. In a typical experiment, participants are exposed to a prime (e.g., a Black or White face) and decide whether a subsequent target word (e.g., 'pleasant,' 'awful') means something positive (press the 'good' key) or something negative (press the 'bad' key). If the attitude prime is strongly associated with a positive evaluation, it speeds up the identification of positive words as 'good' and slows down the identification of negative words as 'bad.' Hence, this *evaluative priming procedure*, first used by Fazio and colleagues in the mid-1980s, gives insight into the extent to which the attitude object is associated with positive or negative evaluations. Wittenbrink (2007) reviews the development and application of these and related procedures and summarizes representative findings.

Response Competition Measures

Other measures take advantage of the interference that results from competing response tendencies. The best known of these procedures is the implicit associations test (IAT) developed by Greenwald and colleagues in the 1990s. It presents two discrimination tasks that are combined in specific ways across a sequence of five steps. To assess attitudes toward African-Americans and European Americans, for example, the first discrimination task may present names that are typical for the respective group and participants are asked to categorize each name as 'white' or 'black.' They do so by pressing a response key assigned to 'white' with their left hand or a response key assigned to 'black' with their right hand. Next, a second discrimination task presents words with pleasant (e.g., love) or unpleasant (e.g., poison) connotations, which participants classify as positive or negative by pressing the left or right response key. At the third step, these two tasks are superimposed and participants press the left key when either a white name or a pleasant word is shown, but the right key when either a black name or an unpleasant word is shown. As in the facilitation paradigms, this task is easier when evaluatively associated categories share the same response key, e.g., when white participants press the left key to categorize white names and pleasant words. Going beyond this assessment of response facilitation, the IAT involves two more steps.

At the fourth step, the assignment of keys to white and black names is reversed, so that participants who first used the left key for white names now use the left key for black names. Finally, the two discrimination tasks are again superimposed, resulting in an assignment of 'black' and 'pleasant' to the left response key and 'white' and 'unpleasant' to the right response key. Of key interest is the speed with which participants can perform the two superimposed discrimination tasks at step 3 and step 5. Do participants respond faster when a given response key pertains either to the pairing of white names + pleasant words or black names + unpleasant words (step 3) than when this pairing is reversed (step 5)? In the present example, a faster response at step 3 than at step 5 is thought to indicate that white names and positive evaluations and black names and negative evaluations are more strongly associated than the reverse pairings. Lane et al. (2007) review the development and application of the IAT, along with representative findings.

Low Tech Measures of Implicit Attitudes

Whereas response time procedures require a high degree of instrumentation and sophistication, other implicit measures are less demanding (for a review, see Vargas et al., 2007). Some take advantage of the observation that attitudes and expectations influence individuals' information processing in systematic ways. For example, people are more likely to spontaneously explain events that disconfirm rather than confirm their expectations; hence, the amount of explanatory activity can serve as an indirect measure of a person's expectations. For example, the number of explanations generated in response to stereotype-consistent versus stereotype-inconsistent behaviors provides an indirect measure of stereotyping. Similarly, people describe expected or stereotype-consistent behaviors in more abstract terms than unexpected or stereotype-inconsistent behaviors. The size of this bias can again be used as an indirect measure to gauge the underlying expectations.

Context Effects on Implicit Measures

To many researchers' surprise, the initial hope that implicit attitude measures may be relatively immune to contextual influences has not been supported (for a review, see Ferguson and Bargh, 2007). Instead, implicit and explicit measures of attitudes typically show the same pattern of context effects. For example, incidental exposure to pictures of liked or disliked members of racial groups shifts racial attitudes on both types of measures, as does exposure to preceding questions that influence which aspects of an attitude object come to mind. Note that these contextual influences cannot be traced to respondents' self-presentation concerns. Respondents lack insight into the rationale of implicit attitude measures and remain unaware of what they disclose about themselves, which renders these measures relatively immune to strategic responding. Instead, context effects on implicit measures reinforce what many researchers inferred from context effects on explicit measures: how people evaluate an attitude object depends on what is on their mind at the time of judgment.

Psychophysiological Measures

A different measurement strategy focuses on the physiological correlates of evaluative responses. Because physiological responses are assumed to be involuntary and hard to control nature, they have long been of interest to attitude researchers who doubted respondents' explicit self-reports. Early uses of physiological measures drew on the observation that strong affective reactions to an attitude object are associated with increased activation of the sympathetic nervous system. Increased sympathetic activation results in increased sweat glands activity, which can be measured by assessing the resistance of the skin to low-level electric currents, a procedure known as *electrodermal measurement*. However, electrodermal responses do not reflect the direction (favorable or unfavorable) of the evaluative response, which limits their usefulness.

More promising are attempts to assess changes in individuals' facial expression in response to an attitude object. Overt facial expressions (like smiling or frowning) may often be observed in response to attitude objects that elicit strong reactions. But these expressions may be intentionally concealed and many evaluative reactions may be too subtle to evoke overt expressive behaviors. Even subtle evaluative reactions are associated, however, with low-level activation of facial muscles that can be detected by *electromyography*. These muscle reactions reflect the direction (favorable vs unfavorable) as well as the intensity of the evaluative response. However, the obtained measures can be distorted by facial movements that are unrelated to the evaluative reaction.

Another approach involves the measurement of brain activity through *electroencephalography*, the assessment of small electric signals recorded from the scalp. This procedure, however, does not lend itself to a direct assessment of positive or negative responses. Instead, it capitalizes on the observation that unexpected stimuli evoke brain wave activity that differs from the activity evoked by expected stimuli. Hence, one may detect if a target object is evaluated positively or negatively by embedding its presentation in a long series of other objects with a known evaluation. The brain activity evoked by the target object will then indicate if its evaluation is consistent or inconsistent with the evaluation of the context objects.

Ito and Cacioppo (2007) review these and other measures, including recent developments in brain imaging techniques, which provide a promising avenue for future work in this area. Throughout, the implementation of psychophysiological measures requires sophisticated technology and high expertise and their analysis poses complex issues of data reduction.

Behavioral Observation

In principle, a person's attitude toward some object may be inferred from his or her behavior toward it. However, people's behaviors are influenced by many variables other than their attitudes. Hence, the attitude–behavior relationship is typically weak, unless other variables are taken into account. Hence, the mere observation of a behavior is a poor indicator of the person's attitude per se and behavioral observation is rarely used as a measurement strategy.

Implications and Future Directions

As this article of attitude measurement issues indicates, responses to attitude measures are highly context sensitive. While this observation is undisputed, its implications are controversial. Some researchers assume that context effects merely reflect some 'noise' that does not call the existence of enduring attitudes into question. From this perspective, attitude measures assess the person's true and enduring attitude plus some temporary contextual influence that gives rise to variation in the expression of an otherwise stable underlying disposition (see Eagly and Chaiken, 2005). Other researchers question the usefulness of the classic attitude concept. They assume that evaluation stands in the service of action. To guide action in an adaptive way, evaluation needs to be informed by past experience but highly sensitive to the specifics of the here and now, turning deplorable context dependency into laudable context sensitivity (see Schwarz, 2007). Independent of these different metatheoretical perspectives, it is increasingly apparent that different attitude measures can give rise to widely diverging conclusions, even when assessed at the same time. For example, subliminal exposure to 'cod liver oil' may facilitate your identification of 'disgusting' as a 'bad' word and may elicit a negative physiological response, yet you report that you think cod liver oil is good for you and you take it regularly. Which of these diverging responses should we consider an unbiased indicator of your 'true' attitude? Each measure reflects a different aspect of a complex phenomenon, rendering the designation of any single one as the only 'true' window on individuals' attitudes counterproductive. Understanding the complex interplay between cognitive, affective, physiological, and behavioral responses in context presents the most challenging issue for future research.

Abstract

Attitudes have generated interest in the social sciences because they have been presumed to exert a strong influence on behaviors. This article reviews the evolution of perspectives on the attitude–behavior link. It begins with early perspectives that assumed a strong attitude–behavior association and then discusses research and perspectives challenging this assumption. Next, various explanations for why attitudes sometimes fail to predict behaviors are reviewed. The article concludes with a discussion of contemporary themes in attitude–behavior consistency research such as the proposition that the processes by which attitudes influence behavior differs as a function of whether behaviors are deliberative versus spontaneous.

Attitude–Behavior Consistency in Historical Context

For decades, the attitude construct has played a central role in many areas of the social sciences. Although definitions of attitude have varied over time and across disciplines, most contemporary researchers have come to view an attitude as a relatively general and enduring evaluation of an object, person, or concept along a positive to negative dimension (e.g., Eagly and Chaiken, 1993; Fabrigar and Wegener, 2010). Attitudes have generated great interest in the social sciences because they have long been presumed to exert a strong influence on behaviors, decisions, and judgments. Thus, in many applied settings, attitudes are measured in an attempt to predict behavior and are the target of persuasive appeals in an effort to shape behavior.

In the early phases of attitude research, the close association between attitude and behavior was largely an article of faith. Indeed, many early definitions of attitude were based on the assumption that attitudes predispose an individual to behave in a certain manner (e.g., Allport, 1935). Likewise, early theories of attitude structure explicitly assumed that behavior was closely intertwined with attitude. For instance, the tripartite theory of attitudes proposed behavior as one of the three fundamental components of attitudes (e.g., Katz and Stotland, 1959). Similarly, early indirect measures of attitudes such as the lost-letter technique relied on directly observable behaviors that were presumed to be manifestations of attitudes (Milgram et al., 1965). Thus, these measures were based on the implicit assumption that attitudes are strongly associated with behaviors.

Despite being the prevalent belief for the first few decades of attitude research, the assumption that individuals typically act in accordance with their attitudes remained largely untested. However, this belief was sharply challenged following the publication of LaPiere's (1934) widely known study on racial prejudice, which appeared to reveal virtually no correspondence between overt behavior toward a Chinese couple and a subsequent measure of attitudes. Subsequent decades produced a number of other studies that appeared to challenge the proposition that attitudes were predictive of behaviors. Indeed, by the 1960s, researchers began to reevaluate the attitude construct and its relationship to behavior. This debate led some researchers to conclude that little, if any, relationship existed between verbal measures of attitude and overt behavior, and some went so far as to recommend abandoning the attitude construct entirely.

Of these various challenges to the utility of the attitude construct, none was more influential than Wicker's (1969) review of 47 studies that appeared to suggest a rather trivial relationship existed between measured attitudes and overt behavior. More specifically, Wicker (1969) asserted that correlations between measures of attitudes and subsequent behaviors rarely exceeded 0.30 and were often considerably closer to zero. Finding an average correlation of 0.15 across studies, Wicker (1969: p. 65) declared that "it is considerably more likely that attitudes will be unrelated or only slightly related to overt behaviors than that attitudes will be strongly related to actions." He further concluded that "Only rarely can as much as 10% of the variance in overt behavioral measures be accounted for by attitudinal data (p. 65)." Despite presenting a rather gloomy outlook on the status of the attitude–behavior link, Wicker acknowledged the possibility that a large number of factors could have led to a reduction in attitude–behavior correspondence and called for a closer examination of their role in this relationship.

The skepticism expressed by Wicker and others regarding the utility of attitudes as predictors of behaviors did not go unchallenged. For example, both Kelman (1974) and Schuman and Johnson (1976) noted that Wicker (1969) based his review on an extremely limited range of domains of social behavior. Indeed, of the 47 articles included in his review, 20 examined attitudes in relation to workplace performance and absenteeism, 16 dealt with racial prejudice, and a small handful (11) assessed miscellaneous topics – several of which contained multiple studies on the same topic. Thus, based predominantly on two domains of social behavior, Wicker reached sweeping conclusions regarding the nature of the attitude–behavior link. These critics noted that when other domains of social behavior were examined, much larger attitude–behavior correlations were often observed. These criticisms notwithstanding, Wicker's review and that of other skeptics of the attitude–behavior link had an undeniable impact on the field and gave rise to what came to be known as the 'attitude–behavior

problem.' Understanding the implications of the apparent weak association between attitude and behavior became one of the central themes of attitude research throughout the 1970s and 1980s.

Explanations for Low Attitude–Behavior Associations

Since the early 1970s, the guiding questions in attitude–behavior consistency research have been when and why measures of attitudes sometimes fail to be associated with behavior. Responses to these questions have taken a myriad of forms. However, at the general conceptual level, most responses to these questions can be broadly classified as falling into one of three broad themes.

Measurement Explanations

One potential explanation for why an attitude measure might be a poor predictor of a behavior is that the measurement procedure might in some way fail to accurately capture the attitude and/or the behavior. Indeed, a number of attitude researchers (e.g., see Kelman, 1974; Schuman and Johnson, 1976) were quick to point out that numerous studies in Wicker's review utilized poor measurement procedures. For example, some investigations actually failed to include measures of attitudes, but rather made assumptions about participants' attitudes. Other investigations obtained measures of attitude that were likely not taken from the same person who performed the behavior. Still other studies examined topics that were socially sensitive and thus participants might not have honestly reported their true attitudes.

Of these various measurement-related explanations for weak attitude–behavior associations, probably the one that has received the most attention in the literature is the attitude–behavior specificity principle. According to Ajzen and Fishbein (1977) there are four elements (i.e., the action, target, context, and time) that contribute to the generality/specificity of an attitudinal or behavioral measurement. An example of these elements might be drinking coffee (i.e., action) with a classmate (i.e., target) in a local coffee shop (i.e., context) at 3p.m. today (i.e., time). According to the specificity matching principle, if the goal is to predict the specific behavior illustrated above, then the respondent should be asked to provide his or her attitude about drinking coffee with a classmate at a local coffee shop at 3 p.m. today. Of course, such a highly specific measure of attitude would not be expected to be a very accurate predictor of an individual's general coffee drinking behavior. Instead, general coffee drinking behavior should be most accurately predicted by a correspondingly general measure of attitude toward drinking coffee. Taken together, to the degree that each of these four elements is of equivalent specificity in a measure of attitude as well as a measure of overt behavior, one can expect to obtain strong attitude–behavior correspondence.

In one of the first demonstrations of this principle, Weigel and Newman (1976) administered a general attitude survey on environmental issues to residents of a New England town. Three months after completing the survey, participants were contacted on various occasions over the next 5 months and provided with opportunities to engage in specific environment-related activities. Consistent with the principle of specificity, their results indicated general attitudes toward environmental issues were relatively poor predictors of any specific environmental behavior (with most correlations below 0.35), but were significantly better predictors of a comprehensive index that aggregated all the individual environmental behaviors ($r = 0.62$). Reinforcing this point, reviews of the attitude–behavior consistency literature have indicated that instances of strong attitude–behavior correspondence were reliably found when measures of attitude and behavior matched in specificity, but weak and inconsistent attitude–behavior correspondence was frequently revealed when mismatches of specificity occurred (Ajzen and Fishbein, 1977).

Clarifying the Role of Attitude in Behavior

Although flaws in measurement can account for many cases in which attitudes have been found to be poor predictors of behaviors, such methodological explanations cannot fully explain variations in attitude–behavior associations. Thus, a number of attitude researchers have sought more conceptual explanations. One general approach has been to more precisely specify how attitudes might influence behaviors and the potential role of other constructs in this process.

Perhaps the best exemplar of this approach, and certainly the most influential, is the Theory of Reasoned Action (TORA; Ajzen and Fishbein, 1980; Fishbein and Ajzen, 1975). This theory begins with the premise that the effects of attitude on behavior are not direct. Instead, the theory postulates that the most proximal determinant of a behavior is a behavioral intention. A behavioral intention represents the amount of effort an individual is willing to exert in order to perform a given behavior. Because intentions are assumed to capture the motivational factors that influence behavior, as intentions increase in strength, so too does the likelihood that a given behavior will be performed. Thus, from the perspective of the TORA, behaviors can largely be conceptualized as intentional actions that typically fall under the volitional control of the individual. Hence, determining an individual's behavioral intention is the key to yielding accurate predictions of behavior. However, it is important to recognize that there are many factors that can intervene and reduce the predictive power of measures of intentions on behaviors. For example, the extent to which a measure of intention and a measure of behavior are of corresponding levels of specificity, the time elapsed between measurement of an individual's intention and a measure of their behavior, and the introduction of new information which may alter the individual's intention can all influence the intention–behavior link.

The TORA further proposes that one of two major determinants of an individual's behavioral intentions is reflected in their attitude toward the behavior. Attitude toward the behavior can be broken down into behavioral beliefs, which reflect an individual's beliefs regarding the consequences of performing a given behavior, and an evaluation of those consequences. The second major determinant of behavioral intentions is subjective norms, which denote an individual's belief that other people important to the individual concerned expect that a particular behavior should or should not be

performed. Subjective norms, in turn, are comprised of an individual's normative beliefs, which represent the belief that other people important to the individual concerned expect the individual to behave in a specific manner, and their motivation to comply with the expectations of others.

The TORA provides a useful framework for understanding why attitudes are sometimes only moderately correlated with behaviors. First, because the effect of an attitude on behavior is indirect, this necessarily sets an upper boundary on the strength of association that can be expected. For example, even if one assumes a relatively strong association between attitude and intention (e.g., $r = 0.60$) and between intention and behavior (e.g., $r = 0.60$), the expected correlation between attitude and behavior will be comparatively modest ($r = 0.36$). Second, in some contexts, one might expect much more modest associations between attitude and intention. For example, when normative pressures for a behavior are strong (a socially sensitive behavior) and subjective norms contradict the attitude, one might quite reasonably expect an attitude to only weakly influence intentions, and thus be only weakly correlated with behavior.

Over the years, a sizeable body of evidence has accumulated supporting the proposed relationships among attitudes, subjective norms, intentions, and behaviors across a wide range of different domains of social behavior (e.g., see Ajzen and Fishbein, 1980; Fishbein and Ajzen, 1975). Furthermore, the efficacy of predicting behavior using intentions rather than attitude was confirmed in a *meta-analysis* of 87 studies by Sheppard et al. (1988), who found an average correlation between intention and behavior of 0.53. Despite the relative success of the TORA, a major theme of subsequent research has been whether attitudes and subjective norms are sufficient to fully explain variations in behavioral intentions or if the prediction of intentions could be improved by the inclusion of additional factors. Among the factors that have been proposed are habit (e.g., Ouellette and Wood, 1998), moral obligations (Gorsuch and Ortberg, 1983), anticipated regret (Richard et al., 1998), and perceived behavioral control (Ajzen, 1985).

Of these additional factors, perhaps the construct that has been most widely accepted is perceived behavioral control. First introduced within the framework of the Theory of Planned Behavior (TPB; Ajzen, 1985), this construct reflects a person's beliefs regarding the difficulty of performing a given behavior. Enacting some behaviors is unhindered by internal or external factors, and thus are instances of high perceived control. In other cases, the performance of behaviors can be impeded by a combination of these factors and thus represent instances of low perceived control. Examples of internal factors include an individual's skills, abilities, knowledge, and adequate planning; whereas examples of external factors might include time, opportunity, and reliance on the cooperation of others. The TPB identifies perceived behavioral control as a separate variable that can influence behavior directly as well as indirectly, mediated by behavioral intentions. The theory predicts a direct effect of perceived control on behavior when an individual's behavior is unlikely to be entirely under volitional control and perceptions of behavioral control are accurate. The indirect effects of perceived behavioral control via intention reflect the assumption that inherent in perceived behavioral control are motivational properties that impact an individual's intentions to perform a behavior. If people believe that a given behavior is outside of their control, behavioral intentions may be reduced even though favorable attitudes and/or subjective norms regarding performance of the behavior exist. This suggests another context in which attitude–behavior correspondence may be weaker than anticipated. If perceived control over performance of the behavior is relatively low, a positive attitude might not be sufficient to produce a strong intention to perform the behavior.

Research investigating perceived behavioral control suggests the addition of this construct has led to significant improvement in the prediction of behavioral intentions as well as actual behaviors (Madden et al., 1992). In line with this, McEachan et al. (2011) recently conducted a *meta-analysis* examining the contributions of perceived behavioral control to the theory of planned behavior. Their data revealed correlations between behavioral intentions and attitudes, subjective norms, and perceived behavioral control ranged from 0.40 to 0.57, and generated a multiple correlation of 0.67.

A second construct acknowledged by many researchers to have an important role in the attitude–behavior relationship is habit (typically operationalized using measures of past behavior; e.g., see Ouellette and Wood, 1998). Most contemporary theorists define habits as tendencies to repeat certain behavioral responses that generally require minimal thought and effort and that occur within the confines of specific supporting contexts. Indeed, research has shown that repetition of a behavior within a specific context frequently leads to the development of cognitive processes that become automatic, thus resulting in minimal effort and attention to perform a behavior. Based on this logic, proponents of the habit construct argued that within contexts that support the development of habits or where specific behavior patterns are already well learned, habits will be strong predictors of future behavior.

Advocates of the habit construct have argued that because the Theory of Reasoned Action assumes that behavior is largely under volitional control of the individual, the theory is better suited for predicting behaviors involving a strong deliberative component rather than those behaviors characterized by habitual or spontaneous responding. Several empirical tests investigating the addition of habit (i.e., past behavior) as a predictor have indicated improved prediction of intentions as well as actual behavior. Most notably, Ouellette and Wood (1998) conducted a *meta-analysis* of 64 studies. Their findings suggested the magnitude of the effect of habit on behavior ($r = 0.39$) was generally equivalent with that of alternative predictors. Although the effect was somewhat weaker than intentions ($r = 0.54$), the data revealed a slight improvement over the effect of attitudes ($r = 0.33$), and a moderate increase compared with the effects of perceived behavioral control ($r = -0.21$) and subjective norms ($r = 0.23$). This suggests that at least some of the low and inconsistent relationships between attitude and behavior found in prior research may be explained when considering the role of habit in behavior.

Attitude Strength

A second conceptual response to understanding variations in the strength of the attitude–behavior link was to focus on more

precisely understanding variations in the underlying cognitive and motivational foundations of attitudes. The central premise of this approach is that although two people might report similar attitudes, the underlying strength of these evaluations might well differ. Thus, when assessing the attitudes of groups of people, it might be inappropriate to assume that the entire sample is reporting attitudes that reflect stable and meaningful evaluations of a particular object. Instead, within any sample of individuals there may only be a subset of people who have relatively well-formed, meaningful attitudes. For this later group, the link between attitudes and behavior might be quite strong, but this strong link might well be obscured by people in the sample who lack strong attitudes on the topic. Indeed, if the group lacking strong attitudes is larger than the group who holds strong attitudes, the overall attitude–behavior correlation might be quite weak. Of course, an important question that naturally arises from this perspective is how one determines whether an evaluation is meaningful and relatively well-formed? To this end, a great deal of research throughout the 1970s and 1980s was focused on identifying the specific properties of attitudes that determine their strength (for reviews, see Fabrigar and Wegener, 2010; Fabrigar et al., 2005; Fazio and Roskos-Ewoldsen, 2005; Petty and Krosnick, 1995; Visser et al., 2006). This research has documented numerous properties of attitudes that have been found to moderate the strength of the attitude–behavior link.

Some of these properties reflected features of the underlying cognitive structure of attitudes. Of these, one of the most widely investigated properties has been the accessibility of an attitude in memory. Attitude accessibility is defined as the strength of the object-evaluation link in memory and is represented by the ease or speed with which the attitude is brought to mind. Numerous studies in both laboratory and field settings have found that greater attitude accessibility is associated with stronger attitude–behavior associations, presumably because of the greater likelihood that an attitude will be activated from memory at the time of the behavior. A second property of cognitive structure that has been studied extensively in the context of attitude–behavior consistency is attitude ambivalence. This construct is defined by the simultaneous possession of positive and negative evaluative responses toward an object. Highly ambivalent attitudes are characterized by both positive and negative evaluations of an object whereas attitudes low in ambivalence reflect predominantly positive or negative evaluations of an object. The majority of studies indicate attitude–behavior associations become weaker as ambivalence increases. Other properties of cognitive structure that have been examined in the context of attitude–behavior consistency include working knowledge, affective-cognitive bases of attitudes, and attitude complexity.

Other determinants of strength explored in the context of attitude–behavior consistency have involved subjective beliefs regarding the attitude or the attitude object. Of these subjective beliefs, the two most widely researched have been attitude importance and attitude certainty. Attitude importance can be conceptualized as the subjective sense of psychological significance an individual attaches to an evaluation or an object (Eaton and Visser, 2008). Increased importance has been found to be associated with higher attitude–behavior consistency across a range of different social behaviors. Attitude certainty reflects the extent to which an individual is confident in their attitude toward a particular object (Tormala and Rucker, 2007). Recently, attitude theorists have proposed that certainty can be decomposed into two conceptually distinct components: attitude clarity (i.e., the subjective sense that one has a clear notion of their evaluation of a given object) and attitude correctness (i.e., the subjective sense that one's evaluation of the object is valid). Research in a variety of domains has found that higher attitude certainty generally translates into stronger attitude–behavior correspondence.

Other determinants of attitude strength have reflected variations in the processes by which attitudes are formed or changed. The first determinant of this type explored in the literature was direct versus indirect experience with the attitude object. Research has indicated that attitudes formed via direct experience are more predictive of behaviors than are attitudes formed via indirect experience. More widely studied has been the extent to which an attitude is formed or changed via extensive cognitive elaboration of attitude-relevant information. Influential theories of attitude formation and change such as the Elaboration Likelihood Model (ELM; Petty and Wegener, 1999) and the Heuristic-Systematic Model (HSM; Chen and Chaiken, 1999) have postulated that attitudes can be formed and changed via highly thoughtful versus nonthoughtful processes. Highly thoughtful attitude formation and change occurs when an individual is highly motivated and able to carefully scrutinize the central merits of information regarding the attitude object (sometimes referred to as the *central route* to attitudes). In contrast, when a person lacks motivation and/or ability to engage in extensive cognitive elaboration of attitude-relevant information, the person will look for simple cues in the formation/persuasion context (e.g., the credibility of the source of the message) to provide a nonthoughtful basis for arriving at an attitude (sometimes called the *peripheral route* to attitudes). The ELM postulates, and subsequent empirical research has confirmed, that attitudes arrived at via careful thought are more enduring and consequential and therefore more powerful determinants of behavior than attitudes arrived at via relatively nonthoughtful processes.

Contemporary Themes in Attitude–Behavior Consistency Research

Since Wicker's influential challenge, the attitude–behavior consistency literature has gradually evolved well beyond its central focus on whether attitudes predict behavior. For the most part, attitude researchers now no longer support or even seriously debate the extremely pessimistic conclusions advanced in the late 1960s regarding the utility of attitudes as predictors of behaviors (e.g., see Eagly and Chaiken, 1993; Fabrigar et al., 2010; Fazio and Roskos-Ewoldsen, 2005). In fact, attitude researchers (e.g., Eagly and Chaiken, 1993) have sometimes expressed surprise that given the vast body of empirical evidence that has accumulated in contradiction to the pessimistic conclusions of the late 1960s, some social psychologists continue to believe that attitudes are only weakly related to behavior. Moreover, it is now recognized that general characterizations of the association between attitudes and behaviors as weak or strong is misleading because conditions

exist in which associations between attitudes and behaviors can be either extremely strong or nonexistent. Thus, attitude–behavior consistency has moved beyond the question of whether attitudes predict behaviors, and even to some extent beyond the question of when attitudes do or do not predict behaviors. In recent years, the focus in attitude–behavior consistency has shifted in an effort to more precisely understand the processes by which attitudes influence behaviors and to more fully understand the processes underlying the effects of various moderators of attitude–behavior consistency.

Distinguishing between Deliberative and Spontaneous Behaviors

Until as recently as the late 1980s, much of the research on attitude–behavior consistency assumed that a single process could be used to describe the manner in which attitudes influence behaviors. Indeed, two of the more prominent theories of the attitude–behavior relationship, the Theory of Reasoned Action (TORA) and Theory of Planned Behavior (TPB), were advanced as theoretical frameworks that could generally be applied under all conditions. However, this notion has been increasingly challenged in contemporary attitude–behavior consistency research.

Of the theories to challenge this assumption, the most prominent has been the *M*otivation and *O*pportunity as *DE*terminants (MODE) model of attitude–behavior consistency (Fazio, 1990; Fazio and Towles-Schwen, 1999). According to the MODE, attitudes serve as guides when making decisions and thus have the potential to influence behavior through affecting an individual's appraisal of their decision alternatives. The MODE model distinguishes between two different types of attitude-to-behavior processes. This distinction revolves around the extent to which choosing a particular behavioral response entails effortfully deliberating between alternative courses of action or a relatively effortless and spontaneous reaction to one's immediate circumstances. When people are motivated and have the opportunity to carefully consider their actions, people will engage in a relatively effortful deliberation of the costs and benefits of performing a specific behavior and thus form an attitude toward the specific behavior. In such a situation, the process by which an attitude influences a behavior will generally resemble the processes as outlined by theories such as the TORA and TPB.

In other situations, people may lack motivation to carefully consider their actions (e.g., if the decision has little importance) or the opportunity to do so (e.g., if distractions are present in the decision environment or the decision must be made very quickly). In spontaneous behavioral contexts of this sort, the MODE proposes that people will be unlikely to carefully consider the positive and negative consequences of a given action and form a specific attitude toward the behavior in question and subsequently a behavioral intention. Thus, theories such as the TORA and TPB may provide a poor description of the processes by which attitudes influence behavior for spontaneous behaviors. Rather, the MODE postulates that more general attitudes toward the target (or targets) of the behavior will be the more consequential attitude (attitudes). Under spontaneous conditions, when an individual encounters the object that is the target of the behavior, the attitude toward that object will be activated in memory (presuming it is sufficiently accessible). This attitude then biases the perception of the object in an attitude-congruent fashion and perceptions of the object will in turn influence how the behavioral situation is construed. Construal of the situation will in turn determine the behavioral response that is undertaken.

To illustrate this process, consider a case in which you are approached by a man who is a member of a particular ethnic group who explains he has lost his wallet and would like you to provide him with $2 to purchase bus fare to get home. If your attitude toward that ethnic group is sufficiently accessible, it will be activated and influence your perceptions of the requestor. A positive attitude might result in you attending to the positive features of the person (e.g., the friendly facial expression and polite wording of the request). A negative attitude might direct your attention to negative features of the person (e.g., shabby clothing). These perceptions in turn could strongly influence if you construe the situation as a sincere request from someone in need (in which case you might well assist him) versus a dishonest ploy to get money (in which case you might decline the request).

Research on the MODE has supported a number of its key premises regarding differences in deliberative versus spontaneous behavior (see Fazio, 1990; Fazio and Towles-Schwen, 1999). For example, in one early test of the MODE, Sanbonmatsu and Fazio (1990) conducted an experiment in which they presented individuals with information regarding two department stores: Brown's Department Store and Smith's Department Store. The information provided about the stores was such that Brown's was described in a positive manner for most of its departments, but its camera department was described as comparatively poor. In contrast, information regarding Smith's was negative for most departments, but information about its camera department was positive. Participants were then asked to indicate which store they would choose if they needed to buy a camera. Motivation at the time of the decision was manipulated by requiring respondents to either justify their responses or not, and opportunity by limiting the amount of time respondents had to make their decision or not.

Following the logic of theories such as the TORA, people should consider the specific positive and negative implications of purchasing a camera from both stores and then form a specific attitude toward purchasing a camera from one of the stores versus the other. This attitude should in turn lead to an intention to purchase a camera from one of the stores. Such a process would suggest that the great majority of participants should select Smith's department store because it has the superior camera department. This outcome in fact did occur when participants had both motivation and opportunity to deliberate about their decisions. However, when motivation and/or opportunity were low, most participants actually selected Brown's despite the fact its camera department was inferior. This finding suggests that people did not consider the specific implications of their behavioral actions, but instead were influenced by their more global attitudes toward the stores (even though those global attitudes implied a non-optimal decision). This later finding is consistent with the predictions of the MODE and not readily explainable using theories such as TORA.

As it relates to attitude–behavior correspondence, findings from tests of the MODE suggest that established theories such as the TORA and TPB remain useful accounts of attitude–behavior consistency when people have sufficient motivation and sufficient opportunity to deliberate about their actions. In such cases an attitude toward performing a specific behavior is likely to be the best predictor of performance of that specific behavior. However, when sufficient motivation and/or opportunity are lacking, more global attitudes toward the target or targets of the behavior might well be more useful predictors of even a specific behavior. In summary, when attempting to predict behavioral responses, the extent to which that behavior is likely to be performed in a deliberative versus spontaneous manner needs to be considered.

Implicit and Explicit Attitude Measures

Another topic that has received significant attention in contemporary attitude–behavior consistency literature is the utility of explicit versus implicit measures of attitudes as predictors of behaviors (for reviews, see Petty et al., 2008). Explicit attitude measures directly ask people to report their attitudes and are represented by various traditional self-report measures that have been commonly used in attitudes research for decades. In contrast, implicit measures do not ask people to directly report their attitudes. Instead, attitudes are indirectly measured, usually using some form of priming paradigm or dual judgment task. Among the implicit attitude measures that have enjoyed substantial popularity in the literature are affective or evaluative priming, the Implicit Association Test (IAT), the Personalized Implicit Association Test (PIAT), the Affect Misattribution Procedure (AMP), and the Go/No Go procedure.

One interesting finding to emerge in this literature has been that implicit measures tend to be better predictors than explicit measures of automatic or spontaneous behaviors and decisions whereas explicit measures tend to be better predictors than implicit measures of more controlled behaviors and decisions (e.g., Dovidio et al., 1997). This basic finding has been demonstrated in a number of studies, but its interpretation remains a matter of much debate. Some have argued that implicit measures and explicit measures capture fundamentally different types of attitudes that are represented in distinctly different memory systems (i.e., implicit/unconscious attitudes versus explicit/conscious attitudes). Thus, these researchers have argued that spontaneous or automatic behaviors are more influenced by our unconscious evaluations whereas deliberative behaviors are more influenced by our conscious evaluations. Others have argued that such measures do not represent fundamentally different attitudes in memory, but instead reflect a single stored evaluation that is manifested in both automatic evaluative judgments (which are comparatively free of motivational concerns and higher level cognitions regarding the evaluation) and more thoughtful evaluative judgments. These more thoughtful evaluative judgments are influenced by the evaluation in memory as well as motivational concerns (e.g., self-presentation concerns and desires to avoid bias) and *metacognitions* regarding the evaluation (e.g., beliefs regarding the validity of the attitude). Thus, these researchers have argued that because spontaneous behaviors should also be less influenced by motivational concerns and *metacognitions*, implicit measures should logically be better predictors of these behaviors. Conversely, because deliberative behaviors are more likely to be influenced by motivational concerns and *metacognitions*, they should be better predicted by explicit measures which are also influenced by these factors.

Processes Underlying Moderators of Attitude–Behavior Consistency

A final theme that has recently emerged in the literature is a greater focus on understanding why specific moderators of attitude–behavior consistency have their effects. For example, as was noted earlier, a number of properties of attitudes have been found to moderate the magnitude of the attitude–behavior link. However, attitude theorists (e.g., Fabrigar et al., 2005, 2010; Fazio and Roskos-Ewoldsen, 2005) have noted that although the list of moderators of attitude–behavior consistency is quite lengthy, the psychological mechanisms responsible for many of these moderator effects are unclear. As such, it is difficult to know to what extent various moderators reflect similar versus distinct underlying processes. Thus, researchers have returned to the study of well-established moderators of attitude–behavior consistency in an effort to better understand the mechanisms responsible for these effects. Indeed, some researchers have postulated that the wide range of moderators in the literature might well be explained by a relatively small set of underlying mechanisms. One recent exemplar of this approach is the Mechanisms Responsible for Prediction and Influence (MRPI) model (Fabrigar et al., 2010; see also Fabrigar and Wegener, 2010). The MRPI proposes that there are three mechanisms that may account for variations in the impact of attitudes on behavior. Building on the MODE, the MRPI postulates that the emergence of these processes depends on whether a behavior is performed in a deliberative versus spontaneous manner.

When people are spontaneous, the theory holds that attitudes influence behavior by serving as simple nonthoughtful cues to appropriate action. Indeed, as discussed earlier, under spontaneous conditions attitudes can provide a simple basis for action even when it might not be logical to rely upon them. However, to serve as a simple cue, an attitude must be activated from memory at the time of the behavior. Thus, under low-deliberation conditions, the theory argues that potential moderators of attitude–behavior consistency will have an effect to the extent that they are related to the likelihood of attitude activation (i.e., attitude accessibility).

When people are motivated and able to be thoughtful, the MRPI postulates that attitude–behavior consistency can be thought of as a type of inference process in which people consider (if the attitude is activated) whether the attitude provides an informative guide for the behavior. That is, people consider whether the bases of their attitude are relevant to the goals of the behavior. If the attitude is seen as a relevant guide, it will influence behavior. If it is judged as uninformative for the behavior, it will have little influence. Consideration of the relevance of attitudes should most likely occur when behaviors are highly deliberative because the metacognitive process of judging the applicability of an attitude and disregarding it or correcting for its influence

requires considerable cognitive resources. Thus, under high deliberation, potential moderators of attitudinal influence will exert effects to the extent that they have an impact on attitude accessibility and/or the extent to which an attitude is perceived as a valid guide to behavior.

To date, testing of the MRPI is still in its early stages. Evidence does exist for each of the processes proposed by the MRPI in the context of some moderators of attitude–behavior associations. However, no single moderator has been examined in light of all the processes and some moderators have yet to be examined in light of any of these processes. Thus, much research remains to be conducted before the utility of the MRPI can be fully determined. However, regardless of the ultimate outcome of these tests, the general approach of more fully exploring the processes responsible for the effects of moderators of attitude–behavior consistency is likely to continue to be a guiding theme in the literature.

Conclusions

The link between attitude and behavior has been of interest to attitude researchers since attitudes first became a topic of systematic empirical inquiry. Although perspectives on this link have varied dramatically over the years, there is little doubt that important advances have been made. The question of whether attitudes can predict behavior has largely been put to rest and influential theories designed to explain the processes by which attitudes exert their influence on behavior have been proposed. Moreover, researchers have documented an impressive array of factors that can account for when attitudes will and will not be useful predictors of behavior, and have now begun to grapple with the mechanisms underlying the effects of these factors.

Attitudes, Political and Civic Culture

GA Almond, Stanford University, CA, USA

This article is a revision of the previous edition article by G.A. Almond, volume 3, pp. 1862–1865, © 2001, Elsevier Ltd., with revisions made by the Editor.

Civic Culture theory asserts that democracy is stable or consolidated when specifically democratic attitudes and practices combine and function in equilibrium with certain non democratic ones. It is a literature which reconciles role theory with citizenship theory, recognizing that civic participation and activity is one of the many roles performed by most individuals and that effective and good citizenship requires a certain harmonization of these roles. 'Strong Democracy,' 'Participatory Politics,' various kinds of 'populism,' tend to deny respect to, and to invade, subject, parental, matrimonial, professional, recreational, and other roles. The concept of Civic Culture as an equilibrium is a dynamic one; that is to say, changes in demography, economy, literacy and education, media exposure and impact, culture, and lifestyle, etc. may transform this equilibrium.

Civic Culture theory asserts that democracy is stable or consolidated when specifically democratic attitudes and practices combine and function in equilibrium with certain nondemocratic ones. It was formulated and tested in empirical research in the late 1950s and early 1960s, years still reverberating with the memories of the rise of Communism and Fascism, the collapse of democracy and the catastrophes of World War II. It drew from a contemporary social science literature similarly influenced by the interwar history of the stalemated Third French Republic, the deeply flawed Weimar Germany, the Austrian and Spanish civil wars, and the breakdown of the Fourth French Republic.

It could point to the long tradition in political theory of 'mixed government,' from Plato and Aristotle through to Montesquieu, which supported this anti-populism and prudentialism. Among the post World War II social science influences were works of Joseph Schumpeter, Paul Lazarsfeld and Bernard Berelson, Edward Shils, Robert A. Dahl, and Harry Eckstein, among others.

Schumpeter rejected the 'classic democratic' assumption of the necessity of an informed, activist, rational public for a genuine democracy, and proposed in its place, an 'elites competing for votes' theory (Schumpeter, 1947, Chapters 21 and 22). This minimalist theory could be reconciled with more realistic assumptions of a relatively ignorant and indifferent demos.

Paul Lazarsfeld and Bernard Berelson, theorizing from their 'panel' voting studies of the 1940s similarly saw democracy as associated with a set of cultural and social conditions having the effect of limiting the intensity of social conflict. These included relative economic and social stability, a pluralistic social organization, a basic value consensus and what we would now call a 'civil society.' They described a democratic equilibrium as involving mixes of involvement and indifference, stability and flexibility, consensus and cleavage (Berelson et al., 1954).

Edward Shils, on the democratic prospects of the new nations, emphasized the importance of a 'widely dispersed civility.' By this he meant a moderate sense of nationality, a degree of interest in public affairs, a consensus on values, institutions, and practices, and a recognition of individual rights and obligations. He wrote " … These qualities should not be intense, and they need not be either equally or universally shared" (Shils, 1960: 387ff).

Robert Dahl's theory of polyarchy, elaborated in 1956 in a full-length contrast with populistic and Madisonian democracy, belongs among these early social science influences on the civic culture. His early characterization of the American political system as providing "… a high probability that any active and legitimate group will make itself heard effectively at some stage in the process of decision … " (Dahl, 1956: 145; see also Dahl, 1970, 1989) reflected the minimalist mood that Dahl shared with the generation that emerged out of the great depression and World War II. At the time that *The Civic Culture* was being written, Dahl's concept of polyarchy already had introduced an empirically grounded and quantitative set of concepts into democratic theorizing. Democracy was not an essence. In its full sense it did not exist, and probably could not exist. Hence the concept *polyarchy* was developed to refer to real political entities which attained measured performance levels on specified empirical dimensions.

Harry Eckstein was the first to emphasize the 'mixed' or paradoxical side of democracy, recognizing the necessity for a democracy not only to represent and formulate the will of the public, but to govern it authoritatively. In his *Theory of Stable Democracy* he describes some of the qualities which enable democracies to reconcile responsible authority and democratic responsiveness. Such reconciliation is facilitated by balances among contrasting qualities; participant behavior is balanced by deference to authority, dogmatism by pragmatism, and the like. Institutionally he attributes democratic stability to the degree to which social authority patterns coincide or are 'congruent' with political ones.

Civic culture theory had the advantage of being formulated in the context of a major empirical investigation informed by this historical experience, and benefiting from this prior research and scholarship. Its results were reported in book form in 1963, in paperback form in 1965; and were reprinted in 1989 (Almond and Verba, 1963, 1965, 1989) and remains in print as of this publication. It was widely reviewed in social science periodicals and in 1980 a retrospective volume was published with critiques of the theory and the findings (Almond and Verba, 1980).

The data were made available in the Interuniversity Consortium for Political and Social Research at the University of Michigan, and have been utilized in many secondary studies.

Four of the five countries that it investigated were chosen because they exemplified democratic stability and instability in the first half of the twentieth century – the United Kingdom and the United States exemplifying stability on the one

hand – Germany and Italy exemplifying democratic instability and breakdown on the other. The fifth, Mexico, was a target of opportunity, selected with the thought that it might provide some insight into problems of democratization outside the North American-European area. The method used in the study, of combining structured and open-ended questions administered to probability samples of national populations, provided a richer set of data specifically responsive to questions arising out of this historical experience and body of speculative theory.

The conception of stable democratic political culture as a 'mixed' political culture received a fuller elaboration than it had been given in the earlier work of Berelson and Lazarsfeld and Eckstein. The mix of democratic political culture was based on political role theory. People in stable democracies were both citizens and subjects, and they needed to accommodate their non political, private, and parochial roles. A thriving, stable democracy consists not only of voters, demonstrators, petition signers, and politician button-holers; but of taxpayers, jurors, and military conscripts; as well as parents, mates, work-persons, voluntary association-members, vacationers, and private, self-involved individuals.

It is this mix of roles – participant as well as subject, non political as well as political – that democratic citizens of a stable democracy must balance and accommodate; and which their institutions must choreograph in a process of converting demands and supports into outputs and outcomes. To shift metaphors, civic culture theory was an equilibrium theory in which political buyers and sellers reach prices at which the political market is cleared. Civic culture theory specified what conditions had to be present in order to clear these markets.

These mixes and balances were located empirically in the British and American cases in the late 1950s and early 1960s – this combination of influentialism and deferentialism, involvement and indifference, conflictual and consensual attitudes, principled and instrumental ones. The relative absence of these balances in the German and Italian cases was noticeable. There was more deferentialism and less participationism in the British case than in the American. A 'reserve of influence' was also noted in the American and British cases, based on the finding that Americans and the British acknowledged the obligation to participate far more frequently than they reported actually participating, This discrepancy between performance and obligation could be viewed as a kind of 'default' mode, a reserve supply of participatory energy available for crises. The civic culture would run cool normally and at a moderate speed, but it had a reserve of influence to draw upon in the twists and turns of democratic politics, as the concerns and interests of different groups of voters were engaged.

By the time the retrospective volume, *The Civic Culture Revisited* was published in 1980 it was evident that British and American civic culture were in trouble (Almond and Verba, 1980, Chapters 5 and 6).

The balance of consensus and conflict had moved toward conflict; pride in nation and confidence in government were down. Participationism had declined. In contrast Germany showed dramatic gains in social trustfulness, confidence in government, and civic competence (Almond and Verba, 1980, Chapter 7). In Italy political alienation and extreme partisan antagonism continued largely unchanged. In Mexico the political culture of ambivalent belief in the legitimacy of the democratic revolution, and the corruption of politicians and office-holders, also still survived (Almond and Verba, 1980, Chapter 9).

That patterns of political culture would change in response to changes in economy, demography, politics and public policy, communications technology, and popular education should not have occasioned surprise. That the exemplars of the civic culture of the 1950s – Britain and the United States – should be showing signs of wear and tear in the 1970s and 1980s; and that the problem child of democracy – Germany – was showing strong signs of an emerging civic culture, were not causes for rejecting civic culture theory. The question was whether the changes observed in the two decades after the civic culture study, were in a direction which sustained or disproved the theory. The evidence was moderately supportive of the theory. Thus, for example, the withdrawal of Johnson from the 1968 presidential race, despite the fact that political tradition would have legitimized another term of office, and the resignation of Nixon from the presidency in the 1970s were clear evidences of American instability; and the political disorders of the 1960s and 1970s were clear evidences of cultural disequilibria of one kind or another – conflict had undermined consensus, the legitimacy of government had declined, the modes of participation had radicalized. In contrast Germany had had several decades of experience of effective political leadership and remarkable economic growth appearing to produce a moderating *koalition-fahig* partisanship, growing popular trust in government, civic obligation, and the like.

The place of civic culture theory in the contemporary theory of democracy is in some doubt. In the continuing theoretic polemic about the nature of democracy anything settling for less than perfection partakes of sin. It was precisely to avoid this commingling of the sacred and the secular that led Robert Dahl to invent the concept of polyarchy and to place the concept of *democracy* somewhat, but not completely, off limits. However Dahl's Polyarchy III (which is the closest to ultimate democracy that he gets) is achieved through increasing the depth and extent of attentive publics within the larger mass public, corresponding to the significant issues confronting the polity and policy elites. Modern information technology makes it possible that this gap between policy elites and the mass public might be significantly reduced (Dahl, 1989: 338ff).

The state of the polemic regarding the competence, rationality, and potential effectiveness of mass publics in contemporary polyarchies is well argued in a symposium held during the 1990s. The merits of the various options – elitism, inventive utilization of information technology, or reducing the scope of politics – are among the issues debated (Friedman, 1999).

Civic Culture theory might have enriched this discussion somewhat by affirming the legitimacy of other than political claims upon humankind. If one views the full range of role demands on the time and resources of humans, how do we choose among them? How do these choices interact? What are

the tradeoffs, synergies, and opportunity costs? How do we weight the claims of the civic world against the demands of profession, family, edification, and pleasure?

Editors' Note

Gabriel Almond, along with co-author Sidney Verba, originated the theory and concept of 'civic culture' in their 1963 book of that title. In addition to its rich conceptual and theoretical insights, the book was also an early exemplar of the need for and value of comparative political research. Almond died on Christmas Day, 2002, and his essay from the first edition is being reprinted here as a legacy entry.

Since the publication of Almond's essay above, *The Civic Culture* (1963) has continued to receive both complements and criticisms of its model, its methodology, its typology, and its conclusions (for useful reviews, see Dalton, 2014: Chapter 12; Verba, 2011). In the event, its value remains its account of the cultural requirements of a democratic polity in particular, and of the relationships between political culture and political regime more generally. And, recent citizen actions in currently democratic, democratizing, and non democratic countries, including those in the Middle East or the successor states of the former Soviet Union, such as Ukraine, have subjected this account to additional important research.

This important research focuses on, for example:

1. intra-cultural change, such as from 'allegiance' to 'assertiveness' among citizens and, relatedly, in citizens' (dis) satisfaction with government and political institutions and officials (see. e.g., Dalton and Welzel, 2014 and Norris, 2011; see also 'Attitudes, Political: Trust,' 'Attitudes, Political and Social Capital,' 'Politics and Participation,' and 'Politics, Protest and Civil Disobedience' in this Section);
2. inter-cultural change and difference, involving consensus but especially conflict between, for example, European- and non-European-based, such as Muslim, cultures (see, e.g., Sniderman and Hagendoorn, 2007);
3. the roles of culture and of cultural change in the sequence of 'human development' involving economic development, culture, behavior, and democratic institutions (Inglehart and Welzel, 2005; see also 'Modernization' in this Section);
4. the theorizing and modeling of relationships involving the causal ordering of beliefs-cultures-preferences and of institutions-regimes (e.g., Inglehart and Welzel, 2005; see also 'Democratic Transitions' and 'State Formation' in this Section) that are capable of addressing, for example, "the fundamental human problem" of "how can a society construct, or preserve, institutions that make self-interested individual action not inconsistent with the welfare of others?" (Munger, 2000: 25);
5. the design, collection, and methodological analysis of multiple country, respondent and time-point datasets capable of implementing the logic and the conduct of comparative inquiry that can help, in part, the research above (see, e.g., the European Social Surveys; the World Values Surveys; Davidov, Schmidt and Billiet, 2011).

Abstract

Scholars of public opinion attempt to describe and account for the politically relevant preferences and beliefs of ordinary citizens, and to assess the political impact of those preferences and beliefs. The development and proliferation of systematic opinion surveys transformed the study of public opinion in the last half of the twentieth century. Analysts have used survey data to examine the social bases, structure, and sophistication of political opinions in elaborate detail, often with an eye toward evaluating the democratic competence of citizens. They have generally been more successful in characterizing and accounting for public opinion than in specifying its role in the broader political process. Efforts to specify the political causes and consequences of public opinion will no doubt be facilitated by the continuing accumulation of survey data over time and space, but will also require scholars of public opinion to make more ingenious and eclectic use of other relevant evidence in combination with survey data.

Scope and Methods

Public opinion has been usefully defined by V.O. Key Jr. as "those opinions held by private persons which governments find it prudent to heed" (Key, 1961). Scholars of public opinion attempt to describe and account for the politically relevant preferences and beliefs of ordinary citizens, and to assess the political impact of those preferences and beliefs. They investigate a wide range of subject matter, including broad ideologies, specific policy preferences, evaluations of political parties and candidates, assessments of self-interest and collective interest, attributions of political responsibility, and attitudes toward social groups and political institutions (Kinder, 1998).

The study of public opinion draws upon and overlaps the study of political psychology, but tends to focus on collective preferences and beliefs in their broad political context rather than on individual mental processes (*see* Opinion Formation, Theory of). For example, the most notable work in the field begins with a psychological account of "how citizens acquire information and convert it into public opinion," but "pays vastly more attention to the social sources of mass attitudes – in particular, the availability of information in elite discourse – than to the largely autonomous operation of people's minds and psyches" (Zaller, 1992: p. 3).

Obviously, which opinions held by private persons governments will find it prudent to heed depends significantly upon the political setting. It should not be surprising that systematic attention to the workings of public opinion has been most common in modern liberal democracies, where the preferences and beliefs of ordinary citizens are supposed to be broadly and routinely consequential, whether through elections of public officials, voting in referenda, interest group activities, or other mechanisms. By the same logic, the proliferation of new democracies in Eastern Europe, Latin America, and Asia since the 1980s may be expected to stimulate unprecedented scholarly attention to public opinion in those parts of the world.

Contemporary studies of public opinion are profoundly shaped by insights and concerns stemming from the rise of mass politics in the nineteenth century and from the intertwined evolution of modern democratic states and societies. For example, Zaller's (1992) influential model of the dynamics of opinion change builds upon Bryce's (1888) distinction between the 'active class' of political entrepreneurs and the 'passive class' of ordinary citizens who have 'been told what to think, and why to think it,' and upon Lippmann's (1922) analysis of the role of the mass media and political elites (including government bureaucrats) in shaping 'the pictures in our head' that govern our reactions to complex and distant public affairs.

While long-standing insights and concerns are readily recognizable in modern scholarship on public opinion, empirical research in the field has been transformed since the 1940s by the development and proliferation of increasingly ambitious and sophisticated opinion surveys. Semistructured in-depth interviews, focus groups, and laboratory experiments continue to generate valuable insights, but their relatively small scale and problems of external validity make them better suited to the study of individual political psychology than of collective public sentiment. By comparison, an opinion survey with several hundred randomly selected respondents can provide a reasonably accurate representation of the preferences and beliefs of millions of ordinary citizens – public opinion on a scale which governments may well find it prudent to heed.

Pioneering Analysis

The pioneering analyses of public opinion based upon survey data were conducted in connection with US presidential elections of the 1940s (Berelson et al., 1954) and 1950s (Campbell et al., 1960). Berelson et al. concluded that election campaigns mostly activate pre-existing political preferences rooted in ethnic, sectional, class, and family traditions and reinforced by social interactions with like-minded

acquaintances (*see* Campaigning: Political; Voting and Direct Democracy). Campbell et al. emphasized the central importance of long-standing psychological attachments to the political parties (*see* Party Identification and Nonpartisanship), while also acknowledging the significance of such short-term forces as Dwight Eisenhower's personal popularity, which overcame but did not supplant the Democratic advantage in party identification dating from the New Deal era. Both of these studies portrayed public opinion as surprisingly thin and unsystematic, arguing, for example, that "many people know the existence of few if any of the major issues of policy" (Campbell et al., 1960: p. 170) and that political preferences "are characterized more by faith than by conviction and by wishful expectation rather than careful prediction of consequences" (Berelson et al., 1954: p. 311).

These uncomplimentary characterizations of public opinion were refined and elaborated in what remains the single most influential (and controversial) work in the field, Philip Converse's essay on "The nature of belief systems in mass publics" (Converse, 1964). Converse's analysis was based on three primary sorts of evidence. First, he showed that survey respondents answering open-ended questions only rarely made spontaneous use of systematic ideological concepts or language. Second, he showed that respondents' political views were only weakly constrained by conventional notions of 'what goes with what': liberals on one issue often took conservative positions on other issues, even within the same policy domain. Third, repeated interviews with the same respondents demonstrated a great deal of instability in their opinions, and the pattern of that instability suggested that it was caused more by random fluctuation than by systematic responses to political events. On the basis of this evidence, Converse (1964: p. 245) concluded that "large portions of an electorate do not have meaningful beliefs, even on issues that have formed the basis for intense political controversy among elites for substantial periods of time."

Civic Competence

The civic competence of ordinary citizens has remained a central issue of scholarly debate in the decades since Converse's devastating analysis. One line of revisionist argument accepted the accuracy of Converse's characterization of public opinion in the USA of the 1950s, but denied its relevance to other times and places. Most notably, Nie et al. (1976) and others argued that the political upheavals of the 1960s had produced a 'new American voter' more sophisticated, more ideological, and more attuned to political issues than the one portrayed by Campbell et al. (1960) and Converse (1964). While this thesis has been subjected to vigorous methodological critiques – and has come with the passage of time to seem at least as time-bound in its own right as the portrayal it aimed to supplant – it focused attention on the potential responsiveness of public opinion to such powerful contextual factors as social change and the nature of political rhetoric.

A newer wave of revisionist scholarship has acknowledged that most citizens in most circumstances are relatively inattentive to politics and uninformed about public affairs, but has interpreted these facts as evidence of "rational ignorance" in Anthony Downs's sense of avoiding costly information gathering in a realm in which individual investment can have only negligible collective consequences. This interpretation is nicely conveyed by the titles of three notable works of the early 1990s: *The Reasoning Voter* (Popkin, 1991), *Reasoning and Choice* (Sniderman et al., 1991), and *The Rational Public* (Page and Shapiro, 1992). These and other works argued that ordinary citizens make sense of the political world despite their lack of detailed information about ideologies, policies, and candidates. In some cases, the emphasis is on how citizens use 'information shortcuts' and 'gut reasoning' (Popkin, 1991) to deal efficiently with political complexity. In others, the emphasis is on the tendency of statistical aggregation to iron out individual errors and idiosyncrasies in mass publics, building upon an argument first set forth by Condorcet in the eighteenth century. This 'extenuationist' literature (to use a label coined by Robert Luskin) has in turn inspired attempts to measure the extent to which information shortcuts and aggregation actually do mitigate the political effects of 'rational ignorance.' For example, Bartels (1996) estimated that individual vote choices in a series of US presidential elections fell about half way between random behavior and hypothetical 'fully informed' choices (imputed to each voter by observing the choices of better-informed voters with similar demographic and social characteristics). Deviations from 'fully informed' behavior at the individual level were mitigated but not eliminated at the aggregate level: on average, Democrats did almost 2% points better and incumbent Presidents did almost 5% points better than they would have if all voters were, in fact, 'fully informed.'

Normative concerns about the quality of public opinion have also led to the development by James Fishkin and others of 'deliberative opinion polls' designed to combine the efficiency and representativeness of conventional opinion surveys with the informative and deliberative aspects of a seminar or town meeting. Rather than simply reporting their existing opinions, respondents are brought together with policy experts, public officials, moderators, and each other to consider political issues in depth. The aim is to find out – and then to publicize – "what the public *would* think, if it had a more adequate chance to think about the questions at issue" (Fishkin, 1991: p. 1).

Political Consequences of Public Opinion

Political scientists have been more successful in characterizing and accounting for public opinion than in specifying its role in the broader political process. The path-breaking study by Miller and Stokes (1963) of representation in the US Congress provided a model for much subsequent research examining the relationship between public opinion and elite attitudes and behavior. However, the basic research design employed in these studies – cross-sectional analysis of the impact of constituents' opinions on the opinions or behavior of individual legislators – is arguably ill-suited to answering questions about the political impact of public opinion in the aggregate, especially in legislative systems marked by strong party discipline or proportional representation, or when crucial policy decisions are made by executives or bureaucrats rather than by legislatures.

An alternative research design focuses on covariation between aggregate public opinion and policy outcomes across political units or in a single political unit over time. The analysis of 'dynamic representation' by Stimson et al. (1995) is an ambitious example of this approach, relating variations in the liberalism of America's 'public mood' over a 35-year period to subsequent variations in the behavior of Presidents, Congresses, and courts. A more specialized literature treats fluctuations in presidential popularity not only as a product of political, economic, and international events (as in the pioneering work of Mueller (1973)), but also as a factor in accounting for the varying ability of Presidents to get things done.

Efforts to specify the broad political causes and consequences of public opinion will no doubt be facilitated by the continuing accumulation of survey data over time and space. For example, the cumulative data file of the American National Election Studies project now includes more than 40 000 individual survey respondents in more than two dozen national elections spanning half a century, while the Eurobarometer series includes biannual surveys since 1973 in each of the member states of the European Union. By merging these enormous survey data sets with aggregate-level data reflecting variations in national economic conditions, electoral laws, party platforms and campaign appeals, policy initiatives, media coverage of public affairs, and many other contextual factors, analysts should be able to illuminate important connections between mass opinion and elite behavior, as well as the role of social and political institutions in shaping those connections.

On the other hand, the availability of richly detailed survey data has probably distracted scholarly attention from crucial aspects of public opinion that are not readily operationalized in surveys. For example, Converse's (1964: pp. 245–246) 'issue publics' – the various minorities of the public whose 'activated' opinions on particular issues of interest are 'expressed in the writing of letters to the editor, the changing of votes, and the like' – have seldom been subjected to detailed scrutiny. Even more notably, the elusiveness of what Key (1961) referred to as 'latent opinion' – the preferences and beliefs politicians *expect* to confront in future elections, after today's policies have had their effects and tomorrow's political opponents have had their say – has discouraged political scientists from giving it attention commensurate with its undoubted political significance. In these cases, among others, scholars will have to be more ingenious and eclectic in collecting and analyzing relevant data if they are to place the study of public opinion more squarely in the mainstream of political science.

Editors' Note

Since the publication of Bartels' essay above, much important research on public opinion has been conducted and published (see Clawson and Oxley, 2013; Dalton, 2014; and many articles in *Public Opinion Quarterly* and in the *International Journal of Public Opinion Research*). Some of this research involves:

1. the definition (nonopinions/opinions), measurement, survey designs (including question construction, questionnaire design, and survey-error reduction), and content analyses of online communications involving public opinion (see, e.g., Berinsky, 2012, forthcoming; Saris and Sniderman, 2004; Weisberg, 2005);
2. the correlates, distributions, and sources of public opinion:
   a. ranging from 'domestic,' such as economic and social (e.g., ethnicity-race and gender) issues through foreign event-policy issues (Berinsky, 2009, 2012; Burns and Gallagher, 2010),
   b. and involving sociodemographic groups; other attitudes, beliefs, and values (such as ideology or party identification); full information or cue use as well as knowledge and sophistication; personality traits; and various media uses (see, e.g., Berinsky, 2012; Saris and Sniderman, 2004; see also Mass Media and Politics);
3. the connections between public opinion and public policy, notably the 'thermostatic' model (Soroka and Wlezien, 2010; see also Berinsky, 2012; Political Representation);
4. dataset constructions and methodological developments capable of analyzing individual- and aggregate-level change and stability of public opinions and of policy connections (see, e.g., Hagenaars and McCutcheon, 2002; Saris and Sniderman, 2004; as well as Political Science and Polling; Pooled Cross-Sectional and Time Series Analyses, in Political Science.

Abstract

The construct of authoritarianism is one of the major attempts in political psychology to understand individual differences in intolerance and prejudice and susceptibility to fascist appeals. The publication of *The Authoritarian Personality* by Adorno, Frankel-Brunswick, Levinson, and Sanford in 1950 initiated a large body of empirical research on the causes and consequences of authoritarianism. The construct has been severely criticized since its inception on both theoretical and empirical grounds. Recent work in this area has made significant progress on some of the empirical issues but substantial theoretical problems remain.

The construct of authoritarianism grew out of attempts by psychologists to understand the mass appeal of fascism in the first half of the twentieth century. As a result of a large body of empirical research, authoritarianism has become one of the major psychological explanations for the persisting finding of generalized prejudice and intolerance: the tendency for negative attitudes toward out-groups to correlate across different targets. It remains one of the most important approaches in the political psychology literature.

Origins

Research on authoritarianism was influenced by the attempts of European psychologists in the psychoanalytic tradition to understand mass support for fascism (Fromm, 1941; Reich, 1946). The major defining work was the publication in 1950 of *The Authoritarian Personality* by Adorno et al. (1950). This book of almost 1000 pages combined psychoanalytic and personality theory with empirical research from in-depth interviews and questionnaires. While the project began as a study of antisemitism, the researchers quickly discovered that antisemitism appeared to be a part of a broader ethnocentrism. They located the origins of this ethnocentrism in basic personality processes as seen from a Freudian perspective.

Adorno et al. argued that punitive child-rearing practices and inconsistent parental affection produce a severe conflict within the young child. The repression of hostility toward the parents is, in adulthood, displaced onto groups perceived to be weak or inferior while authority figures (a generalization from the parents) are deferred to. Another consequence of this psychological conflict is a weak ego, which in turn leads to characteristics such as an unusual adherence to conventional social values, intolerance of ambiguity, and attraction to superstitions. From this perspective, prejudice has little to do with the actions or attributes of the target group but is a consequence of the psychological needs of those high in authoritarianism to direct repressed hostility toward subordinate groups.

Along with their explanation, Adorno et al. developed a paper and pencil measure of authoritarianism. It was labeled the F-scale because it was considered to be an indicator of susceptibility to fascist appeals. Introduced just as quantitative social science research was gaining momentum, an enormous literature soon developed that examined the correlates of authoritarianism, as measured by the F-scale or similar measure. As of 1989 there were well over 2000 publications on authoritarianism and related constructs (Meloen, 1993). Studies cataloged the relationship between the F-scale and social background characteristics, various measures of personality, and a wide range of social and political attitudes (see Kirscht and Dillehay, 1967 for a typical review of this research).

Criticisms

The Authoritarian Personality was subjected to close scrutiny and criticism almost immediately after it was published (see Christie and Jahoda, 1954). Methodologically, problems with the F-scale measure of authoritarianism cast doubt on much of the empirical research. Since all of the questions in this scale were worded so that an agree response indicated authoritarian characteristics, a tendency to agree with questions like this regardless of content (agreement response set) could produce high authoritarianism scores independent of any individual differences in personality. And while the questions in the F-scale were developed to tap the various syndromes hypothesized to make up authoritarianism, it is not clear that the measure reflects the underlying conceptualization. Factor analyses of the F-scale always show the measure to be multidimensional but the factors are always difficult to interpret and never cleanly correspond to the hypothesized components (see Altemeyer, 1981).

Critics also argued that the authoritarianism measure, and possibly the construct itself, was ideologically biased. Although Adorno et al. were clearly responding to the history of fascism in Europe, the growing threat of communism in the 1950s led to concerns about an authoritarianism of the left (Shills, 1954). However, despite observations that communists appeared to possess traits characteristic of authoritarians, there is little empirical evidence to support these claims (Stone, 1980).

Perhaps most importantly, the Freudian-based theory underlying *The Authoritarian Personality* proved far less useful

than the authors thought and as a result research become increasingly divorced from the theory. In addition to the general loss of status of Freudian explanations in empirical social science research, Adorno et al.'s specific explanation of authoritarianism has not fared well. Although quantitative research established relationships between the F-scale, social background characteristics, and social attitudes, evidence on the dynamics and origins of authoritarianism consistent with the Adorno et al. theory proved elusive (see Altemeyer, 1981; 1988; Duckitt, 1989). The bulk of research based on *The Authoritarian Personality* thus consists of short empirical studies with only limited guidance from the original theory. Most of these studies report correlations between measures of authoritarianism and a small number of other individual level characteristics: social background, personality, values, and attitudes.

More Recent Approaches

Several attempts have been made since the publication of *The Authoritarian Personality* to develop alternative explanations for individual differences in prejudice and intolerance. Perhaps the best known of these is Rokeach's research on dogmatism reported in *The Open and Closed Mind* (1960). Rokeach moved from the Freudian perspective of Adorno et al. to a more cognitive explanation based on the structure and function of belief systems. He argued that prejudice and intolerance are a result of closed belief systems that ward off threats by limiting the scope of accepted beliefs and rejecting all challenges. Like Adorno et al., Rokeach developed a measure of dogmatism based on the same methodology of agree–disagree attitude statements. His dogmatism measure was also constructed of a diverse range of statements designed to reflect the various elements of open and closed belief systems.

While research has utilized Rokeach's dogmatism scale, most of it, like research using the F-scale, consists of narrow empirical studies that examine the correlates of the measure. There has been little reported work that has examined Rokeach's conceptualization of open and closed belief systems despite his own detailed and novel explorations reported in the book. In addition, the measurement properties of the dogmatism measure have proved to be no improvement on the F-scale. It too has items that are worded in only the agree direction and the interitem correlations and dimensionality of the measure may be even worse than the F-scale (Altemeyer, 1981).

The most significant new contribution to the authoritarianism literature has been a recent body of research reported by Altemeyer (1981; 1988; 1996). From years of studies using undergraduate students, Altemeyer has both developed a new and more reliable measure of the construct and advanced a new conceptualization based on social learning theory. Rejecting the Adorno et al.'s Freudian explanation, Altemeyer (1988) prefers a simpler conceptualization that sees authoritarianism as a social attitude (or cluster of attitudes) that is learned through interactions with parents, peers, schools, the media, and through experiences with people who hold conventional and unconventional beliefs and lifestyles. His measure of right-wing authoritarianism (RWA) is more reliable and unidimensional than previous scales and has items balanced for agreement response set.

There have been several other attempts to reconceptualize the authoritarianism phenomenon. Kelman and Barkley (1963) argued that high authoritarianism reflects a limited breadth of perspective. Lipset (1960), Selznick and Steinberg (1969), and others have suggested that authoritarianism is a function of social learning associated with lower social class and less educated environments. More recently, Duckitt (1989) has developed a model in which authoritarianism reflects the desire to maintain strong in-group identifications.

Limitations and Problems

In addition to the measurement and theoretical problems discussed above, there are other significant shortcomings of the authoritarianism approach.

How do factors in the social environment exacerbate or moderate predispositions toward prejudice and intolerance? Some researchers have hypothesized that social threats or anxiety will arouse prejudice and punitiveness and encourage support for extreme right-wing parties and even mass violence (Staub, 1989). There is also some evidence from archival and individual level studies that levels of authoritarianism, or the strength of the connection between authoritarianism, prejudice, and intolerance, increase during periods of threat (Sales, 1973; Doty et al., 1991; Feldman and Stenner, 1997). Although there appears to be strong impressionistic evidence that prejudice, intolerance, and support for right-wing groups wax and wane over time, there is nothing obvious in the present conceptualizations of authoritarianism that would help to explain this phenomenon.

More generally, authoritarianism is generally treated as a purely dispositional construct; researchers almost always examine simple additive relationships between measures of authoritarianism and indicators of prejudice and intolerance. This type of approach provides no understanding of how the reality of social and political conflicts – or any other environmental factors – interact with authoritarian predispositions. This leaves authoritarianism a purely 'personality' explanation, with only weak connections to other explanations of prejudice and intolerance.

It is also necessary to make progress on the relationship between authoritarianism and ideology, particularly since the authoritarianism construct is beginning to be used in studies of countries with a history of communist governments. Studies in the USA and Canada consistently find negative relationships between measures of authoritarianism and attitudes toward communism. In Russia, however, researchers have shown that 'right-wing authoritarianism' has been associated with support for communism (McFarland et al., 1992). This relationship can be understood if support for communism in countries like this represents a commitment to the established, authoritarian order. Even so, a positive correlation between 'right-wing' values and communism strongly suggests that the construct of authoritarianism must be defined and measured in a way that allows it to be used in cross-national research.

Conclusions

Despite all of the problems that have been raised with the authoritarianism construct since the 1950s, it continues to be used in research on prejudice and intolerance. Its longevity is, in part, a function of the repeated findings of consistency in expressions of prejudice and intolerance across a wide range of targets. Individual differences account for a significant proportion of the variance in these attitudes and authoritarianism remains one of the major explanations of those individual differences.

Editors' Note

"Authoritarianism" has been defined in at least two major ways in political and social science research. According to the "institutional" definition, authoritarianism is, in particular, a type of government or regime whose few institutions and their incumbents can make and enforce rules that others must obey, and it is, more generally, a context in which power is concentrated and only slightly or completely unrestrained by other actors or organizations (see also Dictatorship). According to the "attitudinal-value-behavioral" definition, authoritarianism is a set of attitudes, beliefs, values and behaviors that are associated with personality characteristics and other factors, and whose origins, measurement, explanations, and problems in research are well discussed by Feldman above.

In recent years, this latter research has developed in important ways (for reviews, see, e.g., Clawson and Oxley, 2013; Gibson, 2008). Five ways involve:

1. the sources, notably socialization, other experiential, and perceived threat bases, distributions, and consequences of authoritarian attitudes, beliefs, values and behaviors (see, e.g., Stenner, 2005; Feldman et al., 2010);
2. the trends in relationships between authoritarianism and (in)tolerance, and in (in)tolerance itself, which may be defined as an individual's recognition that other people have lifestyles and views that differ from her/his own and that they have the right to public expression of them. Several of these studies have questioned whether tolerance of people in different ethnic-racial, including Muslim, and other social groups, and of people with different political or social views has increased, rather than decreased, over time in various countries (see, e.g., Gibson, 2008; Sniderman et al., 2000; Sniderman and Hagendoorn, 2007);
3. the theoretical, conceptual and empirical connections among authoritarianism/(in)tolerance, ideology (see, e.g., Feldman, 2015; see also Ideological Constraint: History and Current Status of the Concept), personality traits, and/or value constructs (see e.g. Cohrs et al., 2005). These personality traits include the "Big Five" of agreeableness, conscientiousness, extroversion, neuroticism, and openness (see, e.g., Mondak, 2010; Gerber et al., 2011). The value constructs refer to seven basic ones of hedonism, power/achievement, security, self-direction, stimulation, tradition/conformity, and universalism/benevolence (see Davidov, Schmidt and Schwartz, 2008; Davidov, Schmidt and Billiet, 2011);
4. the relationships between "institutional" authoritarianism and "attitudinal-value-behavioral" authoritarianism, that is, whether and, if so, then how and why the former precedes the latter and/or vice-versa (see, e.g., Attitudes, Political and Civic Culture; Democratic Transitions and State Formation, Theory of).
5. the conceptualization of authoritarianism within political psychology (see Kessler/Cohrs, 2008; Stellmacher/Petzel, 2005) and its relation to the dual process model in social psychology (see e.g. Duckitt et al., 2002).

Abstract

Attribution is primarily the process of ascribing a cause to an event or explaining the event. Secondarily, the term 'attribution' refers to certain inferences or judgments, such as inferences of personality traits from behavior and judgments of responsibility and blame. Psychological research on attribution was inspired by Heider (1958), who argued that the social perceiver makes sense of the world by attributing behaviors and events to their underlying causes. The rise of empirical attribution research in the 1960s and 1970s was sparked by a focusing and narrowing of Heider's broad model of social perception, generating two main strands of research: attribution as trait inference and attribution as causal explanation. The first strand began with Jones and Davis (1965). They took Heider's idea that people infer intentions from behavior a step further by developing a model of 'correspondent inferences' from a given intentional behavior ('he acted friendly') not just to a corresponding intention but to a corresponding trait ('he is friendly'). The second strand began with Kelley (1967) who developed Heider's insight that causal judgments are pivotal in social perception. Kelley proposed that such judgments are based on a simple information-processing rule: people infer those causes that covary with the event in question. Kelley's covariation theory profoundly influenced attribution research by assuming that (1) people break down causes into internal attributions (something about the agent) and external attributions (something about the situation) and (2) that the internal–external dichotomy generally applies to all behaviors and events alike. Recent theoretical developments emphasize, by contrast, that ordinary people sharply distinguish between (1) attributing *intentional actions* to the actor's reasons and motives and (2) attributing *unintentional behaviors* (e.g., failure, depression) to causal factors internal or external to the agent. This approach considers behavior explanations to be an integral part of people's theory of mind, which views people as intentional agents who act in light of their beliefs and desires. One advantage of this approach lies in its compatibility with work on responsibility attribution, which also takes into account the intentionality of the behavior in question. Another advantage lies in the integration of social-psychological work on explanations with developmental research on children's emerging theory of mind as well as with philosophical analysis of the properties and evolution of folk psychology. A further development suggests that attributions are not just cognitive processes but rather communicative acts. Thus, behavior explanations are altered for impression-management purposes, are responsive to an interlocutor's interest and concerns, and have an immediate impact on others' perceptions and evaluations of the explainer and the agent whose behavior is being explained.

Background

Psychological research on attribution was inspired by Heider (1958), who developed models of attribution for object perception as well as person perception. Heider assumed, following the philosophical tradition of phenomenology, that a perceiver faced with observational data tries to attribute these data to their underlying cause – to an object in the case of sensory data, and to characteristics of the agent or the environment in the case of human behavioral data.

Heider recognized, however, that person perception is more complex than object perception – due to the manifold observational data available and the manifold causes (e.g., beliefs, desires, emotions, traits) to which these data can be attributed. Heider believed that people master this complexity by means of a sophisticated conceptual framework that he labeled 'commonsense psychology' – nowadays also called 'folk psychology' or 'theory of mind.' Using this conceptual framework, perceivers bring order to the massive stream of behavioral data by classifying them and attributing them to mental categories – including motives, obligations, sentiments, and personality traits. For example, certain behaviors are classified as 'intentional actions,' and the perceiver looks for the specific intention underlying each action (what the agent was trying to do).

Heider's research method was philosophical. He relied on conceptual analysis complemented by linguistic examples and thought experiments, but he provided no empirical experiments to test his model. The impact of Heider's work, then, was largely mediated by other researchers, who turned some of his ideas into empirical research programs. The evolution of attribution research can therefore be seen as a selective exegesis of Heider – with different scholars picking up different ideas and developing them in more detail.

This survey begins with a brief sketch of Heider's charismatic work, then turns to the two main strands of post-Heiderian attribution research: trait attribution work and causal explanation work. Finally, recent theoretical developments are addressed that return to some of Heider's original concerns and link attribution research to developmental research on children's theory of mind (*see* Mind, Theories of) and philosophical work on folk psychology.

Heider

Despite his early focus on object perception, Heider's deepest concern was always with the topics of person perception and social interaction. Just like Lewin and Asch before him, Heider recognized that a psychology of social interaction must chart out people's *subjective* conceptions of the social world. At first Heider tried to develop a general theoretical framework to describe these conceptions, but then he realized that such a powerful framework already existed – it was commonsense

psychology, the system of concepts that ordinary people use to describe and understand human behavior. In his 1958 book, Heider thoroughly explored this framework, analyzing such commonsense concepts as *can*, *want*, *try*, and *ought*. Heider's blend of empirical observation with conceptual and linguistic analysis was visionary and unlike anything psychology had seen before – resembling more the tradition of ordinary language philosophy or contemporary cognitive linguistics.

Two major insights stand out from Heider's analysis of social perception. The first is that social perception is a process of reconstructing invariance out of variance. According to Heider, the social perceiver is presented with streams of behavior, and the cognitive system conceptualizes these streams in terms of a network of fundamental concepts, trying to reconstruct the invariances underlying behavior. Heider's notion of invariances encompassed perceptions, intentions, motives, abilities, and sentiments, which are all relatively invariant against the stream of ongoing behavior. Among these invariances, the agent's motives occupied a special role: "The underlying causes of events, especially the motives of other persons, are the invariances of the environment that are relevant to [the perceiver]; they give meaning to what he experiences" (Heider, 1958, p. 81). Heider's second major insight was that the reconstructive process of identifying invariances is a form of causal (i.e., attributional) analysis, rendering judgments of causality one of the primary elements in social perception. According to Heider, the commonsense conception of causality breaks down into two separate models. For one, there is *impersonal causality*, applied to unintentional human behaviors (such as sneezing or feeling pain) as well as physical events (such as stones rolling or leaves falling). For another, there is *personal causality*, applied only to human agents who perform an intentional action (such as cleaning the kitchen or inviting someone to dinner): "Personal causality refers to instances in which *p* causes *x* intentionally. That is to say, the action is purposive" (Heider, 1958, p. 100). For Heider, this distinction between unintentional and intentional behavior was central to commonsense psychology because it guides how people predict, evaluate, and influence social behavior.

In the literature, Heider's distinction between personal (intentional) and impersonal (unintentional) causality is typically portrayed as a distinction between internal (or person) causes and external (or situation) causes of behavior. But Heider did not subsume all internal attributions under the label 'personal causality'; only the attribution of purposive behavior to intentions and motives was characterized that way. The remaining internal causes fall under the 'impersonal' label, because they bring about behavior in a mechanical, nonintentional way. Thus, Heider drew a line between intentional and unintentional events, whereby intentional events are based on a special class of person causes (intentions and motives) and unintentional events can be based on person or situation causes.

Attribution Research after Heider

The rise of empirical attribution research in the 1960s and 1970s was sparked by a focusing and narrowing of Heider's broad model of social perception. Two main strands of research can be identified, each of which used Heider's ideas as a starting point and then developed them in more detail.

Attribution as Trait Inference

Heider theorized about the conditions under which people infer intentions from behavior. In their classic paper, Jones and Davis (1965) took this idea a step further by developing a model of 'correspondent inferences' from a given intentional behavior ('he acted friendly') not just to a corresponding intention ('he tried to be friendly') but to a corresponding trait ('he is friendly'). The model identified conditions that increase the likelihood of such correspondent trait inferences. For example, the social perceiver will be more likely to infer a trait the more the action in question deviates from what is normally seen as desirable, and the more unique (positive) effects it has compared to alternative courses of action. If none of these conditions hold, the perceiver will not infer a correspondent trait but instead attribute the agent's behavior to forces of the situation.

The initial model was limited to intentional behaviors and predicted that people do not infer traits from unintentional behaviors or from behaviors performed under strong constraints (e.g., upon request by an authority). However, subsequent research found that people infer traits even from unintentional behaviors such as mistakes and accidents (e.g., 'he's clumsy') and even when the agent acted under strong constraints. This tendency to make correspondent trait inferences, even from single behaviors, and the parallel reluctance to attribute behavior to situational forces, was later dubbed the 'correspondence bias' or 'fundamental attribution error' (Ross, 1977).

Researchers became increasingly interested in the question as to why people are so ready to infer traits from behavior and what conditions would moderate this bias. The currently dominant models of trait inference postulate a multistage process in which a behavior is identified as a certain type of action, a corresponding trait is then inferred by default, and only subsequent corrections take situational influences into account (Gilbert and Malone, 1995). However, this default trait inference does not occur, for example, when the situational influence is salient or when the perceiver suspects that the agent acted out of ulterior motives. A potential limitation of trait attribution work is the scarcity of studies that examine the frequency and conditions of trait inferences in naturalistic social contexts.

Attribution as Causal Judgment

The second major strand of attribution research was inspired by Kelley's (1967) model of causal attribution. Focusing on Heider's insight that causal judgments are pivotal in social perception, Kelley proposed that such judgments are based on a simple information-processing rule: people infer those causes that covary with the event in question. Specifically, when an agent *A* behaves toward object *O*, the cause of the behavior is perceived to lie in *A* (internal attribution) if few other people behave as *A* does (low consensus), if *A* behaves the same way toward *O* over time (high consistency), and if *A* behaves the same way toward other objects (low distinctiveness). By

contrast, the cause of the behavior is perceived to lie in *O* (external attribution) if most other people behave as *A* does (high consensus), if *A* behaves the same way toward *O* over time (high consistency), and if *A* behaves differently toward other objects (high distinctiveness). For Kelley, the principles of covariation applied equally to behaviors (whether intentional or unintentional) and physical events. His model was therefore embraced by causal reasoning researchers in both social and cognitive psychology.

Empirical tests of the covariation model tended to support it, although this support was limited to experimental settings in which explicitly presented covariation information had an effect on judgments. At the turn of the twenty-first century, no studies had demonstrated that people spontaneously, in everyday situations, seek out covariation information before answering a why question. Moreover, the covariation model makes no predictions about situations in which people lack covariation information (e.g., single observations) or in which they are not motivated to make use of the information (e.g., under time pressure). For those instances, Kelley later proposed additional rules of causal reasoning ('causal schemata'). One of them is the discounting principle, which states that, under certain circumstances, a second cause weakens the plausibility of a first cause. For example, if a student aces a difficult exam, we might explain it by assuming that he studied hard; but upon hearing that he cheated we may no longer believe that he studied hard, thereby discounting the previous explanation.

The problem that Kelley's causal attribution models tried to address was the 'causal selection problem' – how perceivers select particular causes for explaining a given behavior or event. Even though Kelley's models themselves did not completely solve this problem (alternative models were developed later), Kelley's work profoundly influenced attribution research by assuming that (1) people break down causes into internal ones (something about the agent) and external ones (something about the situation) and (2) the internal–external dichotomy generally applies to all behaviors and events alike. This dichotomy proved to be a compellingly simple dependent variable that allowed researchers to explore a variety of interesting phenomena. One of these phenomena is the self-serving bias in explanations (see Miller and Ross, 1975) – the tendency for people to explain their own positive and negative outcomes so as to maintain favorable self-perceptions or public impressions. For example, students would be expected to explain a good grade by citing internal causes (e.g., ability or hard work) and a bad grade by citing external causes (e.g., bad luck or an unreasonable teacher). Another important phenomenon is the actor–observer asymmetry, which is the tendency for people to explain their own behaviors and other people's behaviors in systematically different ways. Specifically, Jones and Nisbett (1972) argued, and later studies confirmed, that people tend to explain their own behaviors by reference to external factors (e.g., 'I chose psychology as my major because *it's interesting*') but explain other people's behavior by reference to internal attributes (e.g., 'He chose psychology as his major because *he wants to help people*').

Some researchers proposed alternatives to the internal–external dichotomy of causes. For example, Weiner introduced two additional distinctions – one between stable and unstable causes and one between controllable and uncontrollable causes – and thereby improved predictions for people's emotions and motivations in the wake of explaining achievement outcomes, health outcomes, and deviant social conduct (see Weiner, 1995). Abramson et al. (1978) introduced another distinction, between global and specific causes, to describe a hopeless explanatory style in depression (*see* Depression). However, most attribution work at the beginning of the twenty-first century still uses a single internal–external (or sometimes trait–situation) distinction.

The focus on internal versus external causal attributions to all behaviors and events alike can be contrasted with Heider's claim that ordinary people sharply distinguish between (1) attributing *intentional actions* to the actor's motivation and (2) attributing *unintentional behaviors* (e.g., failure, depression) to causal factors internal or external to the agent. Heider felt, as an interview in 1976 reveals, that people's attributions of events were adequately depicted in Weiner's model, but that attributions of actions to motives were inadequately treated by contemporary research (Ickes, 1976). A second limitation of contemporary research is that it developed primarily cognitive models of the attribution process, whereas Heider demanded careful attention to the communicative functions of attributions and the language of causality. Some recent theoretical developments have tried to address both of these potential limitations.

Recent Theoretical Developments

Many refinements have been proposed since these original conceptualizations and empirical studies. These have been reviewed by Gordon and Graham (2006) and Malle (2004).

Attribution as Folk Theory of Mind

Over the decades, attribution research has offered increasingly sophisticated information-processing models for the basic internal–external distinction, but it has not examined the distinctions that actually guide people's explanations within folk psychology – an omission that Kelley and Michela (1980) called the central irony of attribution research. The study of people's own concepts and distinctions has recently gained force among researchers who endorse what may be called a folk–theoretical approach to explanations. This approach considers behavior explanations an integral part of people's folk theory of mind and assigns the concept of *intentionality* a central role in these explanations, because people reliably distinguish between intentional and unintentional human behaviors and use distinct modes of explanation for each type of behavior (Buss, 1978; Malle, 1999).

In particular, unintentional behavior is explained by *causes*, perceived as simply bringing about the behavior in a mechanical way (e.g., 'She cried because *she was sad*'; 'He fell because *the floor was slippery*'). By contrast, intentional behavior is primarily explained by *reasons*, conceptualized as the beliefs and desires an agent considers when forming an intention to act (e.g., 'She quit her job because *she felt the pay was too low*'; 'They worked extra hours because *they needed to finish the project*'). Thus, when people offer reason explanations, they presume the agent's awareness of the reason

content and a more or less rational process of forming an intention to act in light of those reasons. According to the folk-theoretical approach, the traditional internal–external dichotomy applies well to people's cause explanations of unintentional behavior but not to reason explanations of intentional behavior. For example, the above reason explanation, 'she felt the pay was too low,' refers to the agent's own belief ('she felt'), but the belief itself has a content that refers to the situation ('the pay was too low'), so it is unclear how this reason should be classified within an internal–external scheme. To analyze adequately people's reason explanations of intentional behavior, new theoretical categories have been developed that take into account the complex conceptual and linguistic nature of reasons (Malle, 1999).

One advantage of the folk–theoretical approach lies in its compatibility with work on responsibility attribution. For example, Shaver (1985) argued that assignments of responsibility and blame are critically dependent on the intentionality of the behavior in question, and so the choice of explanations (e.g., causes vs reasons) often manages assignments of blame. Another advantage of this approach lies in the integration of social–psychological work on explanations with developmental research on children's emerging theory of mind and philosophical analysis of the properties and evolution of folk psychology (Malle et al., 2001). These disciplines have highlighted people's unique conception and explanation of intentional action, and the next generation of attribution research will have to flesh out in detail the conceptual, linguistic, and social nature of these unique explanations.

Attribution as Communication

Heider examined the concepts of commonsense psychology in their everyday conversational context because he was convinced that tools of social perception help people to accomplish their goals in social communication and interaction. Along these lines, innovative work by Hilton (1990) and Antaki (1994) suggests that attributions are not just cognitive processes but rather communicative acts that obey the rules of conversation; that is, behavior explanations are altered for impression-management purposes (e.g., to appear rational or fend off blame). Explanations are also responsive to an interlocutor's concerns and questions (e.g., 'How was this possible?' elicits different modes of explanation than 'For what reason?'). Finally, explanations have an immediate impact on others' perceptions and evaluations of the explainer and the agent whose behavior is being explained.

Future Directions

Promising new directions of attribution research may arise from a merging of the folk–theoretical and communicative approaches. By recognizing people's fine-grained theory of mind and their distinctions between various modes of explanation, researchers can more effectively trace the cognitive as well as communicative functions that explanations serve in social interaction. Classic phenomena such as the self-serving bias, the fundamental attribution error, and the actor–observer asymmetry may then be fruitfully reexamined, not just under laboratory constraints, but within their natural contexts of occurrence. Greater attention to the social context and functional roles of attribution processes may perhaps be the most important desideratum for future research. As a result, attribution theory might lead to powerful applications in the domain of social relations (e.g., conflict resolution, relationship dynamics) and would contribute to the scientific knowledge of both social perception and social interaction, reverberating Heider's (1958) timeless goal of providing a psychology of interpersonal relations.

Abstract

This article surveys the literature on auctions. To a large part it is concerned with revenue and efficiency considerations. It addresses the problems of finding the auction that yields the greatest expected revenues to the auctioneer and that allocates the goods to the bidders which value them most highly. Models with private value, common value, and general value are considered. Open (English, Dutch) and sealed-bid (discriminatory, uniform-price, first-price, Vickrey) auctions are analyzed. The analysis focuses on the strategic aspect of the bidding process, that is, the game-theoretic auction literature will be heavily relied on. The employed equilibrium concept is Bayes–Nash. The theoretical analysis is supplemented by reviewing empirical work resulting from real-life auctions or controlled laboratory experiments. The importance of auctions in designing trading institutions is documented for financial markets.

Introduction

The use of auctions to allocate goods is quite common and has been known for centuries. Numerous and quite different goods are sold by auctions, that is, antiques, fish, flowers, real estate, gold, securities, and oil exploration rights. Cassady (1967) gives a complete list of goods sold by auction. The literature on auctions is enormous, and it is increasing rapidly. It is concerned mainly with revenue and efficiency considerations, namely to find the auction that yields the greatest expected revenues to the auctioneer and that allocates the goods to the bidders which value them most highly. Further issues, like the robustness of auctions, transactions costs, bid preparation costs, and the vulnerability to cheating are addressed rarely.

Definitions

According to Cassady (1967: p. 8), auctioning is

> a unique system of allocating … property based on price making by competition of buyers for the right to purchase.

More formally, Myerson (1981) defines an auction mechanism by (1) a pair of outcome functions, which gives the allocation of the goods and the bidders' fees in dependence of the bidders' strategies, and (2) a description of bidders' strategic plans. According to those definitions, there is a plethora of different auctions. To fix ideas, assume that there are N units of a homogenous good for sale and that each bidder is restricted to one unit of the goods. First of all, open and sealed-bid auctions can be distinguished. An auction is open, if the bids become known to all participants of the auction when submitted. In contrast to this, an auction is sealed-bid, if bidders submit their bids privately. Thus, bidders have no knowledge of the bids of their competitors.

The best known open auctions are the English and the Dutch auction (cf Milgrom and Weber, 1982). In the English auction, the auctioneer raises the price up to the point, where N bidders remain, with the understanding that the N units of the good are sold to the remaining bidders at the last called-out price. In the Dutch auction the auctioneer lowers the price interrupted only by bidders accepting the last called-out price for one unit of the good. The auction ends when all units are sold or a lower price limit is reached.

The best known sealed-bid auctions are the discriminatory and the uniform-price (competitive) auction (cf Smith, 1966; Harris and Raviv, 1981). In the discriminatory auction the N units are allocated to the bidders with the highest price bids in descending order. Successful bidders are charged an amount equal to their bids. Thus, for more than one unit for sale, different bidders pay different unit prices in a discriminatory auction. If there is only one unit for sale, the discriminatory auction is called first-price auction. The rules of the uniform-price auction are the same as those of the discriminatory auction, except for the prices paid by successful bidders. In the uniform-price auction all successful bidders are charged the same price, which equals the highest unsuccessful bid. If there is only one unit for sale, the uniform-price auction is called second-price auction or Vickrey auction. Vickrey (1961) introduced this type of auction.

Allowing for more than one seller, a double auction results. In a double auction sellers submit bids to sell and buyers submit bids to buy. The sellers' (buyers') bids are ranked in ascending (descending) order. The price in a nondiscriminatory double auction is determined by the intersection of the obtained supply and demand schedule. This auction as well as other types may be performed as a discrete-time auction at predetermined times during a trading period, or as a continuous-time auction at any moment during a trading period (cf Friedman, 1991).

The goods sold by auction can be classified with respect to the monetary value that bidders attach to them. Milgrom and Weber (1982) distinguish between goods with private value, goods with common value, and goods with general value. Goods are of the private value type (or of preference uncertainty (cf Myerson, 1981)), if its value to a bidder is a purely personal matter. A painting bought for purely personal reasons provides an example. Goods are of the common value type

(or of quality uncertainty (cf Myerson, 1981)), if the monetary value bidders attach to it is the same for all bidders. This value, however, generally will be unknown at the time the auction takes place. Typically, securities have a future uncertain monetary value. Thus, they are of common value. A good is called to be of the general value type, if its value to a bidder is a combination of private and common values. A painting bought for both personal reasons and later resale could be considered being of the general value type.

Analyzing Auctions

The auction literature can be divided into three groups: *decision-theoretic auction models*, *game-theoretic auction models*, and *empirical studies*. Decision-theoretic auction models deal with the bidder's decision problem in a way which ignores her strategic response to the bidding behavior of her competite. The game-theoretic approach, on the contrary, is based on this strategic aspect of the bidding process. Empirical studies make use of either the decision-theoretic or the game-theoretic approach when examining data sets resulting from real-life auctions or controlled laboratory experiments.

The earliest auction models are of the decision-theoretic type. They are motivated by real-world auction design problems concerning the sale of oil exploration rights (Hughart, 1975) and US Treasury bills (Smith, 1966; Scott and Wolf, 1979). Formal in nature, they assume that bidders are expected utility maximizers, where the expectation is with respect to a subjective probability density function for the lowest accepted bid (cp, e.g., Smith, 1966). In particular, it is assumed that a bidder's action does not affect the realization of the lowest successful bid (cp, e.g., Scott and Wolf, 1979). Despite obvious modeling deficiencies, those early models already succeed in identifying certain effects, which later are proved rigorously within the game-theoretic approach to auction theory.

The earliest game-theoretic auction studies primarily are concerned with the determination of Bayes–Nash equilibrium bidding strategies. The models are quite simple in that they assume symmetric bidders with independent value estimates. Those results are generalized in different directions in order to account for bidders with correlated value estimates, for goods of the general value type (Milgrom and Weber, 1982), and for goods with a resale market (Bikhchandani and Huang, 1989).

Empirical studies of auctions are concerned with the analysis of real-life auction data sets or controlled laboratory experiments. Examples are auctions of Federal leases on the Outer Continental Shelf (Hendricks and Porter, 1988), US Treasury bills (Cammack, 1991), wine (Ashenfelter, 1989), and collectible trading cards over the Internet (Lucking-Reiley, 1999).

A Game-Theoretic Auction Model

For ease of exposition there is only one unit of goods to be sold in an auction. The *auctioneer*, who for simplicity is assumed to be the owner of the goods, sets the auction rules and makes them known to all participants. The auction rules are binding even though it might be in the auctioneer's interest to change them after the bids have been submitted. The auctioneer is risk-neutral, that is, interested in maximizing the expected revenues resulting from the sale of the goods. There are n risk-neutral bidders competing with each other in the auction. When preparing their bids, they do not cooperate. Every bidder i has some private information x_i, a realization of her information variable. Bidders are distinguished solely by their private information; otherwise they are identical. It is assumed that the number of bidders and the joint distribution of all information variables is common knowledge.

In an auction a rational bidder takes the bidding behavior of the competitors into account and behaves strategically. However, a bidder has only incomplete information about the relevant features of the bidding situation. Thus, an auction is to be considered a non-cooperative game with incomplete information among the bidders. To analyze this game the Bayes–Nash equilibrium concept (Harsanyi, 1967/1968) is employed. For that purpose, a bidder's strategy is defined as a real-valued function mapping possible realizations of her information variable into bids. A Bayes–Nash equilibrium (B_1, …, B_n) of bidders' strategies is described by the following properties. B_i maximizes bidder i's expected gains assuming bidding strategies B_1, …, B_{i-1}, B_{i+1}, …, B_n of her competitors and the assumed bidding behavior is correct.

Theoretical Results

Fundamental to the theory of auctions is the bidding behavior under varying assumptions. This naturally includes alternative auction rules. In what follows the Dutch, English, first-price, and second-price auctions will be considered and compared.

The simplest set-up is the one where the good to be auctioned is of private value and the values that different bidders attach to it are independent. This assumption is well suited for goods without resale, but it excludes cases like the painting of an artist whose work has some prestige among collectors.

The Private Value Model

Independent Private Values

Although the rules of the standard open and sealed-bid auctions are quite different, Vickrey (1961) found an astonishing similarity. When comparing the Dutch and the first-price auction, he noted that a bidder would follow the same strategy in both auctions. In either auction, a bidder has to determine a price at which she is willing to accept the good. In the first-price auction this would correspond to her bid; in the Dutch auction this would be the lowest called-out price at which she would claim the good. Thus, the Dutch and the first-price auction are strategically equivalent. A similar argument applies to the English and the second-price auction. In either auction, a bidder would bid her private value. This ensures that she will accept all prices below and no price above her private value of the good.

To be more specific in the first-price auction, consider the decision problem of bidder i. Her expected gains are given by

$$x_i \times \text{Probability of winning} - \text{Expected payments} \qquad [1]$$

where x_i denotes her private value. Note that lowering the bid has two opposing effects on expected gains. The probability of

winning decreases, and the gains from the bid increase. Intuitively, the optimal bid will be such that it balances those two effects, thus maximizing eqn [1].

Since bidders differ only by their private information, bidding behavior can be described by a common bidding strategy B. The resulting bidding strategies in the standard sealed-bid auctions are as follows, where F is the distribution function of X_i:

1. Bidding Strategies (Vickrey, 1961; Harris and Raviv, 1981)
   a. In the second-price auction the symmetric bidding strategy is given by
   $$B(x) = x$$
   b. In the first-price auction the symmetric bidding strategy is given by
   $$B(x) = x - \frac{\int_0^x [F(y)]^{n-1}\,\mathrm{d}y}{[F(x)]^{n-1}} \qquad [2]$$

From this a number of conclusions follow that are subject to empirical testing. Both in the first- and second-price auction, bidding strategies are increasing in bidders' private values. In a first-price auction, bidding becomes more aggressive with an increasing number of bidders. A comparison of first- and second-price auctions yields that a bidder submits a lower bid in the first than in the later auction. This difference in bids is represented by the second term of eqn [2].

Uniqueness of symmetric equilibria can be established (cp Milgrom and Weber, 1982). Furthermore, efficiency is guaranteed in both types of auction, that is the bidder with the highest private value is the one who wins the good.

From the described bidding behavior, bidders' expected gains and the auctioneer's expected revenues can be derived. Both coincide in the case of first-price and second-price auction. This is a special case of the revenue equivalence theorem (Vickrey, 1961; Harris and Raviv, 1981; Myerson, 1981; Riley and Samuelson, 1981).

2. Revenue Equivalence. The auctioneer's expected revenues are the same in the single-unit English, single-unit Dutch, first-price, and second-price auction.

Similarly, a bidder's expected gains coincide in the above mentioned auction types.

Strictly Affiliated Private Values

Suppose that bidders' private values are strictly affiliated, that is, large values of one variable are more likely, when the other variables are large as well. Milgrom and Weber (1982) introduced this generalization of nonnegative correlation. This concept allows for goods of private value, where bidders have some common liking.

Although Dutch and first-price auction are still strategically equivalent, this is no longer true for English and second-price auction. In particular, Milgrom and Weber (1982) established the following ranking of auctions.

1. Auction Ranking. The auctioneer's expected revenues in the first-price auction are never higher than those in the second-price auction. The auctioneer's expected revenues in the second-price auction are never higher than those in the single-unit English auction. The single-unit Dutch auction yields the same expected revenues as the first-price auction.

Similarly, in the second-price auction a bidder's expected gains are smaller or equal to those in the first-price auction.

The Common Value Model

In the common value model the unknown value of the good and bidders' information (about the unknown value) are affiliated. Auctions of financial securities like US Treasury bills and of Federal leases on the Outer Continental Shelf can be analyzed within this framework. The informational effect, however, makes bidding quite complicated and gives rise to the following phenomenon.

Winner's curse

Common value models suffer from an effect called the winner's curse.

> learning that others have bid less than [his own bid] … is bad news about the value of the item being acquired.
> Milgrom, 1987: p. 18

Unsophisticated bidding leads to the effect that the successful bidder tends to be the one who overvalued the goods. Substantial losses in common value auctions are quite often attributed to this effect. Thus rational bidders take account of the winner's curse effect, when preparing their bids. The 'winner's curse' was the subject of a lot of controversy (cf, e.g., Kagel and Levin, 1986). Milgrom (1987) formalizes the winner's curse effect for a sealed-bid common value auction for one unit of the good, where the highest bid wins the auction. A bidder's expected unit value of the goods, when she has won with her bid, is smaller than her expected unit value. Thus, the winner's curse effect can be measured by this difference.

Any information on the unknown common value will weaken the winner's curse effect. In particular, linking the price in an auction to affiliated information of the common value reduces the winner's curse. This is the essence of the linkage principle (Milgrom and Weber, 1982). Reducing the winner's curse effect leads to more aggressive bidding and higher auction prices. Also competition matters, that is, the winner's curse effect gets stronger with an increasing number of bidders.

Independent Information Variables

If the bidders' information variables are independent, the results of the common value model resemble those of the independent private value model. In particular, the auctioneer's expected revenues in the first-price and second-price auction coincide. Similarly, the same is true for a bidder's expected gains in both auctions.

Strictly Affiliated Information Variables

The bidding behavior in the common value set up can be described in the same way as in the private value model. Again, Dutch and first-price auction are strategically equivalent. This, however, is not the case for the English and second-price auction. Fundamental to the analysis is a bidder's expected value of the good given her information and the fact of winning the auction with her bid. This way she takes care of the winner's curse effect. Taking this into account, existence and uniqueness

of symmetric equilibria can be established (cf Milgrom and Weber, 1982).

The central results of the common value auction literature concern the ranking of auctions, the auctioneer's information policy and the information aggregation property of auctions. All those results rely on the comparison of symmetric equilibria of the respective auctions. The basic results are as follows:

1. Auction Ranking (Milgrom and Weber, 1982). The auctioneer's expected revenues in the first-price auction are never higher than those in the second-price auction. The auctioneer's expected revenues in the second-price auction are never higher than those in the single-unit English auction.

If the auctioneer has private information about the unknown common value, she may use this fact to influence the outcome of the auction. She may commit to supplying information publicly in order to increase revenues. There is a whole range of possible information policies. Milgrom and Weber (1982) mention complete revelation (fully reporting of all information), censoring (reporting of favorable information only), randomizing (reporting after having added noise to the information), and concealment (no reporting of private information).

2. Information Revelation (Milgrom and Weber, 1982). The auctioneer's policy of revealing any affiliated information publicly and completely raises her expected revenues in the first-price auction, the second-price auction, and the single-unit English auction.

There has always been the question of whether the price of a good of unknown value reflects (aggregates) the dispersed information of market participants. Under certain assumptions this could be answered in the affirmative in the case of auctions.

3. Information Aggregation (Wilson, 1977). The winning bid in a first-price auction converges almost surely to the common value V as the number of bidders n goes to infinity.

The General Value Model

The general value model gives results in much the same way as the common value model. In particular, the auction ranking and the information revelation results hold true. However, the information aggregation property relies on the simple structure of the pure common value model and thus does not generalize.

Empirical Results

There is an increasing number of studies which provide tests of auctionmarket behavior by means of experimental methods or real-life auction data sets (field data). Whereas the experimental approach allows for controlling a specific auction model including informational assumptions, the field approach provides a test of auction theory in situations where most theoretical assumptions are unobservable.

Quite often, experimental studies are concerned with the independent private values model, in which predictions are being tested. The results obtained are mixed (cf Smith, 1991; Kagel, 1995, and their citations for the following). Bidding behavior is characterized by deviations from the strategic equivalence of first-price and Dutch auctions and second-price and English auctions, respectively. In particular, in first-price (second-price) auctions bidders submit higher bids than in the corresponding Dutch (English) auctions. Consequently, revenue equivalence does not hold. However, as predicted by theory, individual bids are strictly increasing in bidders' private values. As concerns comparative statics, increasing the number of bidders leads to more aggressive bidding on the bidders' part in first-price auctions. When introducing affiliated private values in experiments, the resulting bids could be better explained by Bayes–Nash bidding behavior than by alternative ad hoc bidding models.

Fundamental to experimental work in the common value set-up is the study of Smith (1967), who examines individual bidding behavior in discriminatory and uniform-price auctions. His results are consistent with the predictions of auction theory. He establishes that bids in the discriminatory auction are lower than those in the uniform-price auction and that the same is true for the auctioneer's revenues. Other results are less supportive of auction theory (cf Kagel and Levin, 1986; Kagel, 1995, and his citations for the following). As predicted by theory, individual bids are strictly increasing in bidders' information. However, comparative statics might fail. This is the case in second-price auctions, where increasing the number of bidders leaves bids unaffected.

In general, Bayes–Nash bidding behavior in sealed-bid auctions is questioned by strong winner's curse effects especially for inexperienced bidders. Furthermore, the common value auction rankings could not be confirmed in experiments. Due to the winner's curse effect, sealed-bid auctions yield higher revenues than English auctions. Even information revelation can be affected by the winner's curse effect. Kagel and Levin (1986) find that information revelation reduces average revenues, when the number of bidders is high. Only for smaller numbers of bidders, the theoretical predictions of information revelation could be confirmed. This effect applies to sealed-bid as well as English auctions. Thus, in first- and second-price auctions theoretical predictions are valid only when the winner's curse effect is weak.

Early results of field data support auction theory. For example, Tenorio (1993) establishes that in the Zambian foreign exchange uniform-price auction average revenues are higher than in the corresponding discriminatory auction. Lucking-Reiley (1999), on the contrary, reports a failure of revenue equivalence for auctions of collectible trading cards over the Internet. He finds that revenues in the Dutch auction are higher than those in the first-price auction. With respect to English and second-price auctions, however, the data support revenue equivalence. This contrasts sharply with the results of independent private values experiments.

Double Auctions

Since the nineteenth century, trade at organized exchanges to a large extent was conducted by means of double auctions. Nowadays, double auctions are important tools for computerized trade. They also serve well for the organization of markets for natural gas as well as for electric power networks. The theoretical analysis concerning double auctions is much more involved than that of one-sided auctions. Determination

of Bayes–Nash equilibrium is complicated, if at all feasible. Often the analysis gives rise to a multiplicity problem. For that reason, the theoretical analysis centers around the independent private values model for a single indivisible unit. Satterthwaite and Williams (1993) give results for particular sealed-bid nondiscriminatory double auctions. For m risk-neutral sellers and m risk-neutral buyers, symmetric Bayes–Nash equilibria are determined. Convergence of equilibria to ex post efficiency as both the number of sellers and buyers increase is shown to hold.

However, due to the above mentioned technical problems, the analysis of double auctions is done almost always by means of empirical or experimental studies (cf, e.g., Friedman and Rust, 1993; Section Analyzing Auctions).

Application to Financial Markets

Interest in the market institutions that govern the trade of financial securities grew rapidly during the last decades of the twentieth century. Along with the successful introduction of new exchanges, the trading rules at existing exchanges were examined more closely. Common to all those activities is an interest in the price formation process under alternative trading rules. An important example of this approach is the discussion of the design of the US Treasury bill auction, one of the most important auctions of financial securities. Every Monday the US Treasury auctions a previously announced quantity of Treasury bills maturing in 91 and 182 days, respectively.

Since the late 1950s there has been quite a controversy concerning the design of this auction. This controversy started with a proposal from Milton Friedman to change the Treasury bill auction from discriminatory to uniform-pricing. The reasons given in favor of this proposal were quite different in nature. They ranged from revelation of bidders' true demand curves and an increase in the number of bidders to discouragement of collusion under uniform-pricing. They did not, however, include an increase in the Treasury's average revenues from a sale under uniform-pricing. In fact, the early opponents to this proposal argued by a reduction in revenues through a change from discriminatory to uniform-pricing. Several years later, models of the decision- and the game-theoretic type lent additional support to the Friedman proposal.

In that respect, the results of Smith (1966) and Milgrom and Weber (1982) on the superiority of uniform over discriminatory pricing in terms of auctioneer's expected revenues were especially successful. Despite the fact that a completely satisfactory theoretical model of the Treasury bill auction is not available yet, those results made the Treasury reconsider the Friedman proposal. Those considerations led to experimentation with a uniform-price auction in the 1970s. However, the Treasury retained the discriminatory rules. Only after the Salomon Brothers Inc. admission of violating the US Treasury auction rules, the experiments were taken up again in September 1992 for the 2-year and 5-year note auctions (cf Bikhchandani and Huang, 1993). Experimentation ended in a decision effective with the 11 February 1998 auction to auctioning all bills using the uniform-pricing rules.

Conclusion

The basic game-theoretic auction model gives rise to a number of strong results which have been subject to empirical and/or experimental tests. Naturally, the question arises as to whether those results are robust with respect to a relaxation of assumptions. Unfortunately, there are several assumptions which, when relaxed, give rise to different results. There are a number of factors which have to be dealt with. First, risk neutrality matters. When allowing for risk aversion on the bidders' part, the expected revenue comparison will yield different results. For example, in models with both risk-aversion and strictly affiliated information variables, the established ranking of first- and second-price auctions with respect to expected revenues fails to hold. Only in special cases (e.g., independently and identically distributed (i.i.d) information variables) general results can be established (cf Milgrom and Weber, 1982).

Second, multiunit demand by bidders changes results dramatically. Endogenizing quantity, for example, as in the case of a share auction, might result in a multiplicity of equilibria and a substantial lower expected sale price than in comparable unit auctions (cp Wilson, 1979). Third, in auctions of financial securities bidders usually meet more than once. The introduction of this phenomenon produces all effects that apply to repeated noncooperative games. Finally, a number of features cannot be solved in the outlined theoretical auction model due to mathematical complexities. It is in those cases that one has to rely on controlled laboratory experiments in order to draw conclusions.

Audience Measurement

James G Webster, Northwestern University, Evanston, IL, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Audience measurement entails regular assessments of the size and composition of media audiences. These are presented as syndicated reports used by media industries. Measurement services use questionnaires, diaries, meters, and/or servers to quantify people's exposure to mass media. All methods of data collection are affected by error, including sampling, nonresponse, and response error, as well as error in the production of reports. Audience measurement is a specialized kind of market research that is deeply enmeshed in the media systems of most industrialized nations. These measures, which include broadcast audience ratings, play an important role in shaping popular culture.

Audience measurement, as the term is commonly used, refers to regular assessments of people's media use. These data often result in estimates of the size and composition of audiences, like television audience ratings, that enable advertiser supported media. Audience measurement can be thought of as a specialized form of market research that is deeply enmeshed in the media systems of most industrialized nations (Anand and Peterson, 2000). It quantifies popularity, guides the allocation of billions of dollars in advertising worldwide and, in doing so, shapes the media environment and popular culture.

Uses of Audience Measurement

The major impetus for audience measurement is advertising. By the late nineteenth century, most newspapers and mass circulation magazines had begun to sell space to advertisers. The value of space was determined largely by the number of readers who would see each publication, and by extension each ad. Paid circulation served as a reasonable surrogate for the size of the readership. Many publishers, however, made inflated claims about their circulation, undermining the confidence of advertisers. To make print media credible, in 1914 the industry created the Audit Bureau of Circulations, an independent organization that verified circulation. To this day, such audits continue in the United States and many other countries around the world.

The growth of radio in the 1920s presented new challenges. Unlike print, there were a few traces of the radio audience, save for fan mail or the sheer number of receivers being sold. For radio to be a viable advertiser-supported medium, the industry needed to authenticate the size and composition of audiences. The problem was especially pressing in countries like the United States and Australia that relied on advertising to fund broadcasting (Balnaves et al., 2011). To provide reliable estimates of the number of people listening to specific programs, the industry sponsored audience surveys. By the 1930s independent research firms had begun to produce what were called 'ratings' (i.e., percentages of the population tuned to a particular program or station). These made the audience visible and allowed advertisers to buy spot announcements in radio with a degree of certainty. When television and other forms of electronic media emerged later in the century, similar mechanisms for measuring the size and composition of audiences were quickly put in place (Beville, 1988). By the 1980s, as advertiser support became more widespread, most European countries put similar systems in place (Gunter, 2000).

Today, advertising is a multibillion dollar business. Audiences are bought and sold like commodities. In many countries, these transactions are made possible by a dominant firm that supplies measurements for a particular medium. Advertising expenditures are typically guided by the cost of reaching various audience segments. In a business world increasingly interested in target marketing, research firms have been called upon to produce ever finer demographic distinctions, as well as data on lifestyles, levels of engagement, and product purchases.

Curiously, audience ratings describe something that has already happened, while most advertising expenditures are made in anticipation of audiences that have yet to materialize. This odd system works because, in the aggregate, media audiences are quite predictable. For example, advertisers and networks know the total number of people who are likely to watch television at any time during the year, and negotiate ad prices on that basis. The stability of mass behavior has also allowed researchers to identify various 'law-like' features of audience formation (e.g., Goodhardt et al., 1987; Webster and Phalen, 1997). Web use appears to follow similar law-like patterns (e.g., Easley and Kleinberg, 2010), although advertisers often pay after the fact as a function of audience impressions or 'click-throughs' (Turow, 2011).

The fact that advertising is a major source of revenue for most forms of media (e.g., print, radio, television, the Internet, etc.) has embedded audience measurement in the operation of these industries. Obviously the system places a premium on audiences that will be attractive to advertisers, either by virtue of their sheer size or other desirable characteristics. Content, therefore, is evaluated with an eye toward its audience-making potential. Moreover, broadcasters pay careful attention to how audiences 'flow' across an entire schedule of programming, relying on structural factors to deliver people to their program offerings. Web publishers exploit hyperlinks and recommendation systems in a similar way. In all of these endeavors, audience measurement is needed to manage and sell the audience. In fact, a good case can be made that audience measurement is a necessary condition for the emergence of any form of advertiser supported media (Ettema and Whitney, 1994).

Even in social systems not fully committed to advertising, audience measurement can become a fixture. Public service broadcasting around the world must often justify its existence by demonstrating that it has an audience (Ang, 1991; Gunter, 2000). Here the techniques of audience measurement are similar to those in fully commercial systems, although they may involve the use of more 'qualitative' measures that assess the appeal or usefulness of media materials (Gunter, 2000). Similarly, government officials concerned with good or bad media effects often relate these to people's exposure to good or bad content (Webster and Phalen, 1997).

Measurement in the Digital Media Environment

Since the 1990s, there has been explosive growth in digital media. This has affected older media, like television, by greatly increasing the number of channels and 'on-demand' options available to viewers. It has also created new ways for users to find, view, download, and share media over the digital networks. These developments pose a challenge to traditional methods of measurement by fragmenting audiences and enabling anywhere anytime media consumption.

Prior to the arrival of digital media, virtually all forms of audience measurement depended on drawing a sample of users to estimate the population. This is a 'user-centric' approach to measurement. As competition for audiences has grown, each new channel or Web site has claimed a piece of public attention. As a result, audiences, which used to concentrate on a few outlets, have been fragmented into smaller and smaller groups. This, coupled with the advertiser's desire to reach more narrowly defined audiences, has taxed the ability of samples to keep pace and increased the likelihood of sampling error – a topic addressed below.

Digital media have also enabled the growth of nonlinear technologies, like digital video recorders (DVRs), video-on-demand (VOD), and Web sites that allow users to stream or download media at will. Further, many of these are available on multiple platforms like computers, tablets, and smart phones, allowing users to fetch media anywhere at any time. As a result, it is no longer possible to rely exclusively on scheduling information to determine what media each person is exposed to.

These challenges are mitigated, to some extent, by harnessing the servers that power digital media. They include the computers that (1) provide content to users, by delivering web pages, videos, or other media; (2) enable access through the Internet service providers; and (3) place display ads across multiple Web sites to deliver impressions. In the process, servers can record each user action, which forms the basis for a new way to measure audiences. This is a 'server-centric' approach to measurement.

Each approach, the user-centric method and the newer server-centric strategy, has strengths and weaknesses. Generally speaking, user-centric methods do a better job of assessing the traits of individual users (e.g., age, gender, etc.) and allowing measurement firms to track media consumption across platforms (e.g., print, broadcast, Web, mobile, etc.). However, since they use samples it is difficult to accurately estimate the audience for smaller outlets without undue sampling error. Server-centric methods avoid the problem of too small samples because they see the actions of everyone who uses the server. In theory they provide a census of media use, although in practice all members of the relevant population may not be visible to the server. More importantly, they cannot see who is visiting the server, unless visitors have provided that information. While that is sometimes the case, for example with 'social media' sites, it is often difficult to accurately describe the characteristics of the users. Moreover, servers cannot see beyond their associated digital networks, making it difficult to assess cross-platform media use.

Measurement companies have devised solutions to many of these problems, though none is without its own drawbacks. Often, data are 'fused' to create a hybrid of user- and server-centric information in an attempt to capture the best of both worlds. Unfortunately, true 'single source' systems that measure all the desirable variables (i.e., user traits, product purchases, moment-to-moment multi-platform media use) across a very large sample or population are costly, can impose undue burdens on respondents, and are therefore rare.

Methods of Audience Measurement

Methods of audience measurement are closely tied to the use of user-centric or server-centric approaches. The latter, more traditional approach, offers greater flexibility about who is studied and how they are measured. As a type of survey research, user-centric measurement confronts issues common in sampling and statistical inference. Its distinctiveness comes from the methods it uses to measure the behavior of audience members. One of the three techniques is typically employed: questionnaires, diaries and meters. Server-centric methods limit who can be studied and confine measurement to actions that can be tracked or inferred from server usage.

The first regular surveys of radio audiences were conducted using telephone interviews. Respondents were called at home and asked either what they were currently listening to (i.e., telephone coincidental method) or what they had listened to in the recent past (i.e., telephone recall method). Both techniques are used today. In fact, telephone coincidentals were historically regarded as the most accurate way to measure broadcast audiences and served as the standard against which other methods were judged (Beville, 1988).

The advent of radio audience measurement forced print media to go beyond circulation as the sole indication of readership. Because a single copy of a magazine or a newspaper might well be read by more than one person, circulation alone seemed to understate the audience for print. The industry eventually adopted survey research to better estimate readership. Personal interviews were conducted in which respondents were shown stripped down copies of various magazines and asked if they recalled reading them. Alternatively, to economize on time and increase the number of publications that could be assessed, respondents were asked to sort cards containing magazine logos and indicate which of these were read.

Today, more and more survey work is being done over the Internet. Respondents, who are either recruited or volunteer, fill out to questionnaires online. This method provides some flexibility in questionnaire design, allowing researchers to

introduce visual materials or scripted clarifications. Using the Internet to administer questionnaires can offer fast turnaround times and be relatively inexpensive. However, since these techniques are limited to those who have Internet access and are willing to cooperate, making inferences to larger populations must be done with caution.

Diaries are small booklets in which respondents keep a log of their radio or television usage throughout the day. Typically, diaries are kept for a week, though time periods of different durations are possible. Diaries are a relatively inexpensive data collection technique and, properly filled out, contain a wealth of information. However, many people are reluctant to accept a diary or are unwilling or are unable to make accurate entries. In a world of push-button radios, multi-channel television, and remote control devices, completing a diary can be a burdensome task. Diaries tend to overrepresent the use of popular outlets or programs that come easily to mind and underrepresent the number of sources that a diary-keeper actually uses. Nonetheless, diaries are a common measurement technique for producing local radio and television audience reports (Webster et al., 2014).

Many of the problems associated with diaries can be solved by the use of meters. These devices attach to a receiver and automatically record the source to which the set is tuned. By the early 1940s, Arthur Nielsen had developed such a device and had placed it in a panel of American households to produce national radio network ratings. Household meters were eventually adapted to the new medium of television. While household meters provide a relatively accurate measure of set usage, they are expensive and offer no information about who is actually using the set. With advertisers increasingly concerned about demographics, the latter is a serious shortcoming.

To provide information about viewers, meters were adapted so that people could identify themselves by pressing a button. These 'peoplemeters' were put into service in the United States and most European countries in the 1980s (Webster et al., 2014). Newer peoplemeters are capable of detecting what content is being viewed, eliminating reliance on program schedule information. They do this by detecting an electronic code embedded in the signal, sometimes called a 'watermark,' or by actively comparing the digital signature of the signal to a library of digital media. Today, peoplemeters are the preferred method of television audience measurement in much of the world.

Conventional peoplemeters are attached to television sets, and are therefore unable to measure out-of-home media use (e.g., radio) or cross-platform use. To remedy that problem, measurement companies also use portable peoplemeters (PPMs). These are either built into pager-like devices or wristwatches that respondents wear throughout the day. They 'listen' for an inaudible code (i.e., a watermark) in the audio portion of a broadcast signal, and credit listenership accordingly. PPMs are then docked at night to be recharged and cleared of the information they contain. This technology is used to measure radio audiences in larger markets. It can also capture other forms of media use (e.g., TV viewing) and so holds promise for studying cross-platform behaviors.

With more and more media use migrating to the Web, measurement firms also meter personal computers. Respondents are asked to load measurement software on their own computers, which records the various pages that the user visits and reports that to the research company. These data are aggregated to describe the number and type of people who visit the Web sites. They also support analyses of how audiences flow from one site to another. Like other exercises in metering, this is a user-centric approach that depends upon the cooperation of sample members.

As noted above, a powerful new way to measure Internet use is to monitor servers. These computers see and record the actions of all those using the server. Learning something about the identity of the visitor is the biggest challenge in server-centric measurement. A variety of techniques are used. Servers will note the IP addresses of the visitors. That may reveal something about their location. Identities can sometimes be inferred by the kinds of materials a user accesses. Most importantly, servers routinely place 'cookies' on the browsers of visitors. These are small computer files that contain a record of what a user did on the site, and serve to identify them as repeat customers. Cookies can also be used to track users across Web sites and target advertising. These practices raise questions about user privacy and are the subject of regulation that varies from country to country.

Servers also manage the traffic on most broadband distribution systems. Some firms aggregate data from Internet service providers to estimate Web site traffic. Cable and satellite systems often stream digital video signals into subscribing households, which are managed by 'set-top-boxes' (STBs) attached to TV sets. When properly programmed, STBs can record channel usage. They become the functional equivalent of household meters, except that they are present in millions of homes. The census-like scope of the sample eases the problem of measuring fragmented audiences. When STBs are used to estimate television audiences the data must be carefully weighted to account for the fact that many homes and television sets are not attached to these digital networks.

Sources of Error in Audience Measurement

There are four sources of error in audience measurement: sampling, nonresponse, response, and production. The first three are, again, problems commonly associated with survey research. The last includes a variety of issues that have to do with bringing a saleable research product to market.

Most syndicated audience measurement is based on some form of probability sampling. Abundant digital media and the ensuing audience fragmentation, make sampling error a persistent problem. In world where some media subsist with a fraction of 1% of the total audience, even a sample with tens of thousands of respondents, quickly becomes too small to accurately estimate the audience for smaller outlets or unpopular products. The error may be random, but it is unacceptably high relative to the estimate. Unfortunately, the cost of some measurement devices (e.g., meters) and the diminishing marginal returns associated with increases in sample size have forced difficult compromises on sample size and allowable levels of sampling error. Often, unpopular offerings are simply 'below minimum standards' for reporting. Servers that monitor millions of users can help provide the needed granularity, but with the limitations noted above.

There are also potential problems of response. Written forms of feedback (e.g., self-administered questionnaires,

diaries, etc.) often suffer from low rates of response. Further, as people become increasingly leery of telemarketers, telephone survey completion rates are threatened. All these lead to concerns about nonresponse (i.e., the people providing data are systematically different from those who don't). Even among those who agree to cooperate, there may be problems with the quality of their responses (e.g., response error). Diaries are particularly prone to response errors, as the flood of modern media simply overwhelms the reporting capabilities of even the most conscientious respondent. These errors can be nonrandom. For example, because diaries systematically favor popular media, they can produce reliable results of questionable validity. The accuracy of self-reported media use has become a contentious issue in some academic circles (e.g., Dillipane et al., 2013; Prior, 2013).

The information collected by interviews, diaries, meters, and servers can be thought of as raw material that must undergo a production process to become a saleable product. Data must be coded and checked for obvious errors. Missing values are occasionally imputed using a process called ascription. New information must be added. For example, the characteristics of server users might be inferred by fusing it with other data sets. Responses from underrepresented or overrepresented groups are often assigned a mathematical weight in a process called sample balancing. Finally, data must be aggregated and projected to create population estimates. Such production processes can introduce errors. Sometimes, it is human error. Sometimes it is applying a less than perfect mathematical correction to the data (Webster et al., 2014).

Institutional Aspects of Audience Measurement

In most developed countries, audience measurement is a business that sells research reports or data to multiple subscribers. Sometimes, as is the case in the United States, firms compete openly for clients. In many countries, however, the consumers of audience measurement create a 'joint industry committee' (JIC) that specifies what measurement services are required and awards a multiyear contract to a sole supplier. Under either system, it is common to see one company become the dominant supplier of the 'currency' within a medium. As such, their reports take on the air of quasi-public, official documents. Though various errors in the data mean the numbers are not nearly as 'hard' as they appear, the organizations that use them have little alternative but to treat them as such. And an enormous amount rides on those numbers. The process of allocating billions of dollars in advertising and programming resources is informed, some would say tyrannized, by audience measurement. This affects the kinds of media that are available and, more generally, how entire media systems operate (Ang, 1991; Napoli, 2011; Turow, 2011).

The institutional significance of audience measurement has not gone unnoticed. In the 1960s the United States Congress held hearings into the quality and consequences of the American broadcast ratings industry. Public scrutiny induced the industry to create an ongoing council to audit and accredit ratings research methods, as well as sponsor industry-wide methodological research (Beville, 1988). JICs are also a forum for reviewing research methods. For these reasons, and because audience metrics are used by powerful institutions with competing interests, it is probably the case that no supplier of audience measurements can drift too far from truthful reporting without sowing the seeds of its own destruction.

Even so, much about audience measurement is negotiable and left to industry consensus. The very definition of exposure to media has changed over time and from method to method. For example, in the US the currency for valuing television advertising used to be program ratings. Advertisers, however, were more interested in how many people saw their ads. So in 2007, the currency became commercial ratings plus 3 days of replays, called 'C3s.' Today servers capture more information, which can be parsed in so many ways, that industry consensus about the definition and utility of metrics is a source of ongoing discussion. Social media, for example, allow research firms to track what people say about programs and products. These 'social listening' data can form the basis of metrics on 'engagement,' though just how they will be used remains to be seen. New metrics, once they are adopted, can alter the way media industries operate (Napoli, 2011).

By its very nature, audience measurement is reductionist. Critics have rightly charged that it fails to capture the idiosyncratic, lived experiences of media users. Conventional forms of audience measurement tell us little about what sense people make of the media use and how that use affects them. Some also charge that measurement turns people into commodities by lumping them into categories where one person is the functional equivalent of all others in the group. These groups are then sold to advertisers at some 'cost-per-thousand.' At best, these practices are dehumanizing. At worst, it is argued that the entire enterprise manipulates and ultimately victimizes audiences (Ang, 1991; Turow, 2011).

Alternatively, audience measurement can be seen as exercising a democratizing influence on popular culture. Material that is successful in the marketplace proliferates, while content that is unpopular fades away. While this notion of cultural democracy is oversimplified, it has been argued that measurement empowers audiences by casting them in a form to which institutions can and do respond (Ettema and Whitney, 1994; Webster and Phalen, 1997). Newer social media, which allow people to express their likes and dislikes, share links, and recommend content, extend the impact of measurement. These activities are supported and rendered visible by 'user information regimes,' such as search engines and recommender systems, that aggregate user data. The metrics they produce affect both the production and consumption of media (Webster, 2014). One way or another, it can certainly be said that audience measurement helps shape popular culture.

Abstract

In this article, the authors provide a historical overview of audience research spanning theoretical perspectives from the hypodermic needle model, the transition to British Cultural Studies, and on to postmodern conceptualizations. Applying an interdisciplinary lens, the article provides summaries of pertinent studies in anthropology, cultural studies, and sociology that explore how audiences understand, interact, and use media as part of their daily lives. In addition to the historical background, the article also explores specific subfields in new media, feminist, and global audience research. It concludes with insights into how the field is assessing new developments in social class and reality television.

The Beginning

The notion of audience has been largely derived from the image that media producers have of the actual, or the intended, people or groups of people that they imagine as the main recipients of their products. Media products – newspapers, television shows, films, radio broadcasts – are for the most part manufactured with the aim of capturing the attention of audience members. Often this interest is commercial – when media can capture the attention of particular audiences, their producers can sell this attention to various advertisers who may profit from this exposure. Scholars, therefore, are often rancorous in their disapproval of the commercial nature of the very concept of media audience.

Current audience research comes out of this tradition. At first, a 'hypodermic needle' model of media influence was prevalent among media scholars. This asserted that audience members were powerfully influenced directly by media exposure ('injected' with media 'messages,' so the metaphor goes). This model posited an essentially passive audience, and a media full of clearly understandable content with only one meaning.

This theory of powerful influence and simple media content was supplanted by the work of Paul Lazarsfeld in the 1930s. Lazarsfeld headed the Bureau of Applied Social Research, affiliated loosely with Columbia University, in the 1940s (he later became a professor of sociology at the University). Along with Elihu Katz, Lazarsfeld elaborated the minimal effects model in *Personal Influence* (1955). This work was a more general study of the influence of media on a variety of areas of peoples' everyday lives. It became famous for elaborating the 'two-step' flow model of the influence of media on the audience. Instead of directly and powerfully influencing people, Katz and the study confirmed the idea that media effects, rather than being powerful and evil, were actually for the most part rather minor and noninvasive, mediated through the more important effect of opinion leaders.

The limited effects model was influential in audience research throughout the 1960s. However, by the 1970s, this model was frequently criticized. For example, Todd Gitlin set forth a direct, vitriolic critique of limited effects theory generally, which has been widely read and cited (1978), and which had an important influence on audience research since. In this article, he accuses Lazarsfeld, Katz, Klapper, and other limited effects theorists of misconceiving the problem of media effects. By conceptualizing an 'effect' too narrowly and concretely, Gitlin claimed that researchers missed many less-measurable ways in which the mass media influences its audience. Much of Gitlin's critique of the limited effects model has been picked up today by researchers studying the audience from a culturally contextualized perspective, influenced by anthropological and sociological methods. Nonetheless, the two-step flow model remains relevant in a variety of fields including advertising (e.g., Carr and Hayes, 2014), journalism (e.g., Farnsworth et al., 2010), and information sciences (e.g., Case et al., 2004). As Neuman and Guggenheim (2011) observe in their *meta*-analysis, in recent years, scholars addressing new media are drawing attention to the ways in which the dramatically expanded set of choices facing media audiences necessitate a reconsideration of the central theoretical premises of the media effects paradigm.

British Cultural Studies

The contemporary tradition of critical media audience analysis can largely be traced back to scholars associated with the Centre for Contemporary Cultural Studies in Birmingham. Stuart Hall, David Morley, Angela McRobbie, Paul Willis, Dick Hebdige, and Roger Silverstone have all done work that looks at media audiences not as isolated phenomena, but as individuals and groups of individuals who must be studied in the context of the rest of their lives, and whose nature as a part of the media audience is only one segment of an overall set of cultural practices that characterize their identities. Also emphasized in cultural audience work has been the multilayered nature of texts as well as the complexity of how they are received.

Perhaps the first work to bring together textual and audience analysis from these new, critical perspectives was Stuart Hall's essay about television reception, entitled 'Encoding/Decoding in the Media Discourse' (1973). In this work, Hall theorizes both the complex nature of the meanings 'encoded' primarily in the television text, and the necessarily separate, but equally complex nature of the process by which viewers decode these messages. This seminal article paved the way for the more empirical audience studies which were produced in its wake by cultural audience researchers. Audience research carried out in

 http://dx.doi.org/10.1016/B978-0-08-097086-8.95010-4

this tradition emphasizes overall the ways in which the media are part of culture, and concomitantly, the way in which audience reception of media is only one facet of the way an entire cultural system influences those who live within it.

David Morley's work has been particularly influential. He has authored two famous studies, *The Nationwide Audience* (1980) and *Family Television* (1986). In *The Nationwide Audience*, he looked at the way people of different occupations, social class statuses, and ethnicities interpreted a television news program differently. Even a supposedly 'objective' news show, he found, was open to different interpretations made by different types of audiences. In *Family Television*, Morley took the family locale of the television audience seriously. He and his research team went into the homes of families and both interviewed them about television and observed them watching it. Through this research, Morley was able to convey about the gender dynamics of the family audience for television. One of the phenomena he commented on was the way husbands rather than wives often commandeered the remote control, enabling them to make many of the family viewing decisions.

Morley's work, and the work of other cultural studies researchers, helped to shift scholarly thinking about the media audience from a scientific paradigm, which attempted to measure audience exposure and effects, to a more holistic one which looks at audiences in the context of their everyday lives. As a result of this paradigm shift, the impact of media on audiences became viewed as a broad phenomenon. Rather than searching for more narrow, measurable influences of media, cultural researchers began examining the narratives embedded within media, and looking at how these are interpreted and indeed adopted by audience members in the course of many activities in their lives. Audience research became less focused solely on 'audiences' per se, and has expanded to include the many uses of culture and media we all have in postmodern society. For example, in *The Export of Meaning*, Liebes and Katz looked cross-culturally at the ways in which audiences in different countries, and members of different ethnic and religious groups within each country, interpreted the same episodes of the prime-time soap opera Dallas, which had become a global phenomenon, being broadcast worldwide and achieving an avid following in many different national and cultural contexts. They found striking ethnic and religious group differences in how these audiences read the very same episodes of this popular television show. For example, Israeli Arabs and Russian immigrants were defensive about the American way of life pictured in the show, and attempted to shield their children from it, while others in cultures closer to that pictured read it more as nonthreatening, simple entertainment.

Third Generation Audience Research

The intellectual turn toward 'third generation' research with its focus on 'postmodern' audiences began in cultural studies during the late 1980s and, according to Pertti Alasuutari (1999), emphasizes that "… there isn't really such a thing as the 'audience' out there; one must bear in mind that the audience is, most of all, a discursive construct produced by a particular analytic gaze" (p. 6). However, the definitive statement regarding the place of the postmodern audience in media studies did not emerge until the mid-1990s when Ien Ang (1995) began promoting a critical ethnographic methodology in response to the theoretical needs created by the changing nature of media audiences. Echoing the conception of postmodernity recognizing reality to be an unstable proposition, Ang notes that the state of knowledge regarding television audiences is always in flux. She writes, "What matters is not the certainty of knowledge about audiences, but an ongoing critical and intellectual engagement with the multifarious ways in which we constitute ourselves through media consumption" (Ang, 1995: p. 52). Furthermore, she adds, "Acknowledging the inevitably partial (in the sense of unfinished and incomplete) nature of our theorizing and research would arguably be a more enabling position from which to come to grips with the dynamic complexity and complex dynamics of media consumption practices" (Ang, 1995: p. 67). This postmodern position slowly became the centerpiece of current conceptions of the audience.

Despite the diversity of empirical analyses associated with such work, three basic strains of reception research can be considered as third generation (Grindstaff and Turow, 2006). The first type of reception study attempts to understand the 'decoding' processes associated with television programming; Jhally and Lewis' (1992) *Enlightened Racism* examining audience reception of *The Cosby Show* is an example. They find that reception of the 'Cosby Show' varies with race: African-American viewers are largely ambivalent about the show because it challenges racial stereotypes while simultaneously displaying a standard of living out of sync with the material realities of the black audience, while white viewers are largely positive about the show because it reinforces the American myth of a meritocratic society and thus downplays the continued existence of structural barriers based on race. In *African American Viewers and the Black Situation Comedy: Situating Racial Humor*, Robin Means Coleman (1996) builds on the work of Jhally and Lewis by exploring the diversity associated with a qualitative examination of African-American reception of racially charged situation comedies. The data indicate that some African-Americans think mainstream society believes the representations on television create negative consequences for African-Americans, others think the representations of African-Americans have a positive impact, and others do not think there is a relationship between the representations of African-Americans and the perceptions of mainstream society. The second type of reception work is primary focused on the behavior and interpretations of television fans like Henry Jenkins' (1992) *Textual Poachers*. Borrowing Michel de Certeau's concept of 'poaching,' Jenkins vehemently rejects the dominant stereotypes of fans and shows that fans use material borrowed from popular media to establish subcultures. Jenkins continues this work and adapts his thinking to the new media environment in his more recent book, *Convergence Culture* (2006), which is discussed below.

The last type of reception research examines the consumption of media in the context of a larger social milieu. For example, Andrea Press and Elizabeth Cole (1999) use focus groups to examine the relationship between class subjectivity and the reception of television content. The study produces three important findings: (1) the discourse of pro-choice

middle-class women mirrors the discourse of prime-time television in which abortion is presented as appropriate for only the lower classes; (2) attitudes among pro-choice working-class women vary by class identification; and (3) class divisions are less important than shared beliefs among pro-life women. These findings indicate that the role of categorical identity in audience reception is more complex than previously believed. Similarly, in *New Media Audiences* (1999), Ellen Seiter uses a variety of qualitative methods to paint a more complex picture of the relationship between television and various segments of the American middle-class audience. In particular, Seiter (1999) asserts that middle-class individuals with lower levels of socioeconomic status and higher levels of educational attainment "cannot afford the luxury of indulging a love of popular culture, for fear that they will appear uneducated" (Seiter, 1999: p. 131). As the title of Seiter's (1999) book indicates, however, by the end of the twentieth century scholars were already beginning to confront 'new media audiences.'

New Media Audiences

Initially, theoretical work responded to traditional media's 'diversifying in form and contents' by interpreting new media audiences through a postmodern framework asserting digital technology only exacerbated existing trends making audiences 'less predictable, more fragmented, and more variable' (Livingstone, 1999: p. 63). Yet, rather quickly, many scholars began claiming that something was different about new media audiences. For example, in the influential *Convergence Culture: Where Old and New Media Collide*, Henry Jenkins (2006) argues that contemporary audiences are now defined by their willingness to 'make connections among dispersed media content,' and, as a result, 'consumption has become a collective process' (pp. 3–4). Although Jenkins' theoretical work is widely regarded as significant, much of the earliest empirical research addressing new media audiences were largely guided by the belief that digital age inequality could be addressed through exclusively structural means like expanding fiber-optic networks to ensure the Internet access (for an excellent review of this research, see Livingstone, 2005).

More recently, however, the focus has shifted from issues of access to issues of usage and cultural engagement. Cross-national research examining the relationship between school-aged children and the Internet usage confirms that behavior tends to vary with socioeconomic location. For example, Sonia Livingstone's (2009) mixed-method examination of school children in the United Kingdom finds that for some "the internet is an increasingly rich, diverse, engaging, and stimulating resource of growing importance in their lives; for others, it remains a narrow and relatively unengaging if occasionally useful resource" (Livingstone, 2009: p. 57–58). Yet, access only explains some of the inequality created by new media. As Seiter (2005) notes in an ethnographic study of children and the Internet, closing the technology gap is an 'easier task to address than the wider and deeper deprivations' in society at large (p. 101). Even if access is unconstrained by economic concerns, audience behavior would remain stratified because the availability of the cultural competencies needed to interact with new media is related to socioeconomic status.

Research examining the relationship between young adults and new media finds similarly class-stratified engagement. In her research, Eszter Hargittai and her coauthors find that the tendency to accumulate cultural capital online is related to socioeconomic status using a variety of quantitative data. In a study examining the online behavior of individuals belonging to 18–26 years of age, for example, Hargittai and Hinnant (2008) observe that individuals with higher levels of education and those from materially privileged backgrounds use the Internet for 'capital-enhancing activities,' defined as the frequency with which individuals visit Web sites related to high-status Internet consumption such as political news, economic news, health news, stock prices, or travel information. Recent research addressing the use of social networking Web sites produces similar findings. For example, Danah Boyd (2011) examined the changing cultural preferences associated with the massive shift from MySpace to Facebook; she concludes by noting, "In some senses, the division in the perception and use of MySpace and Facebook seems obvious given that we know that online environments are a reflection of everyday life. Yet, the fact that such statements are controversial highlights a widespread techno-utopian belief that the internet will once and for all eradicate inequality and social divisions" (2011: p. 37).

Like Boyd, many scholars examining new media audiences reject the conceptual division separating mediated behavior from everyday practice. For example, in *Personal Connections in the Digital Age* (2010), Nancy Baym argues that, rather than conceptualizing social cues as something lost when one moves from 'real' to mediated social life, they should be treated as variable; media providing more cues are considered 'rich,' whereas those providing fewer clues are considered 'lean' (2010: p. 9). This work is rather characteristic of empirical analyses of new media audiences in that a social constructivist approach is married with a soft technological determinism to acknowledge the innovative uses of new media and the tendency for existing social relations to be recreated online.

Feminist Audience Research

Feminist audience research now constitutes a sizable body of work with its own history, subfields, and criticisms. Feminist audience study began at the theoretical level with Laura Mulvey's seminal piece about film spectatorship, *Visual Pleasure and Narrative Cinema* (1975), in which Mulvey challenged the notion that audiences unilaterally watch classical Hollywood film. Using the concepts of psychoanalytic theory, Mulvey develops the notion that a 'male gaze' dominates the spectator position in classical Hollywood cinema. Framing gendered audiences as distinct and worthwhile of separate attention pioneered decades-long discussion on the way women view and interact with media.

Later feminist audience analysis broadened Mulvey's discussion of female audiences by including both traditional media as well as specialized 'female' genres. One of the most influential authors to take 'women's media' seriously was Janice Radway. In *Reading the Romance: Women, Patriarchy, and Popular Literature*, she provided a powerful understanding of the way Midwestern women used romance novels, which like

much women's media had formerly been considered too 'trashy' for scholarly attention, as a form of escape from the daily demands of their lives. Using interviewing and ethnography of a group of romance readers, Radway illustrated how women fans found great value in romance novels, admiring the portrayal of strong and independent heroines.

Radway's work was innovative for a myriad of reasons, including her qualitative social scientific study of the *audience* in addition to the text, and her focus on 'women's' genre previously deemed trivial for scholastic attention. By talking with women on their own terms and using their own language and space, Radway was able to understand how women used romance novels to evade household duties and claim time to indulge their own needs and fantasies.

Press (1991) continued in Radway's tradition with her influential book, *Women Watching Television: Gender, Class, and Generation in the American Television Experience*, exploring the ways in which women watch and connect with television. Rather than assuming 'one' female audience, Press sought to understand the way class and generation varied the viewing experiences by interviewing women of different ages in both the working class and the middle class. In doing so, Press documents the differing role that television plays in reinforcing our culture's hegemonic values, finding that "[P]opular television images represent certain social groups, issues, and institutions systematically and repetitively in a manner that often reflects the position of these groups within our society's hierarchical power structure" (1991: p. 27). These findings were a critical juncture for feminist audience research as emerging researchers began combining the contributions of both Press and Radway. While Radway's work validated that female genres warrant scholarly attention, Press brought to light that women's audiences are not unidimensional and that other variables, such as socioeconomic status and generation, must be considered.

Other scholars have explored how 'postfeminist' audiences contextualize and interact with various media. Drawing on Judith Butler's (1990) theory that sexual, economic, and racial facets complicate the category of 'woman,' postfeminism emphasizes a multidimensional female audience. Postfeminist theory suggests that feminist audience researchers must develop a complex theory of the relationship between culture, politics, agency, and women's consumption (Tasker and Negra, 2007).

A leader in researching and theorizing postfeminist audiences, Angela McRobbie questioned how women in today's media environment interact with content that assumes feminism as a 'spent force' that must be both 'taken into account' but framed as though it has already 'passed away' (McRobbie, 2004: p. 256). Her recent works (2007, 2009) focus on the way female audiences negotiate education, earnings, sexual power, and fashion to maintain an aura of femininity while challenging hegemonic masculinity. In particular, her contribution to audience research conceptualizes the absence of critique from today's female audiences who may not have the power to react when their voice is "called upon to be silent … as a condition to her freedom" (McRobbie, 2007: p. 34).

Other scholars have also looked at the way in which postfeminist audiences interact with media. Akass and McCabe (2004) document fans' reaction to the show *Sex in the City* through the lens of feminist critique. New media scholars (e.g., White, 2006, 2009, 2010) have explored 'postfeminist' expression in the public sphere through online forums. Tasker and Negra (2007) allege that postfeminist culture is "exemplified by the figure of a white, middle-class, heterosexual woman" and does not take into account the varied experiences of women. International scholars (Lemish, 2010; Lemish and Reznik, 2008; Parameswaran, 2002; Hegde, 2011) have attempted to bridge this gap by broadening the idea of female audience to look not only at the U.S. and Western audiences, but to look more globally and to understand issues of transnationalism and imperialism as they affect female audiences worldwide.

Global Audiences

The study of global audiences starts largely in response to the 'cultural imperialism' thesis that analyzes media as an instrument of cultural domination, reflecting uneven flows and exchanges between the West and the rest of the world. Canonical studies of cross-cultural audiences (Ang, 1995; Liebes and Katz, 1990; Gripsrud, 1995) challenge the simplicity of this rhetoric based on the misconception of passivity on the part of the local audiences (for a more detailed critique of the cultural imperialism thesis, see Morley, 2006). Far from producing a homogeneous global culture, audience studies have shown that media products moving across national boundaries are often reinterpreted according to local cultural grids. By insisting that international audiences were neither powerless nor uncritical to American television shows, this pioneering research further supports active audience theory on a global scale. However, despite the fact that global audiences have agency to reinterpret or reject what is offered, they have rather limited power to decide which programs are imported in the first place. The United States is still the major media exporter to the global market, even though its relative dominance is declining. The postcolonial approach reminds international media scholars that they must balance a romanticized vision of audience empowerment with a reconstructed politic of media manipulation.

McMillin (2007) notes that postcolonial and critical audience research needs to move beyond the 'cultural imperialism' frame to ask a wider range of questions about international audiences. Based on a mobile and multisited ethnography, Abu-Lughod (1999) studies Egyptian TV drama as a key institution that stitches audiences together for the production of national culture. She watches television and discusses its meanings with two different groups: (1) women in the villages of a rural, underdeveloped region of Upper Egypt and (2) women who work as domestic servants in Cairo. These television dramas provide common reference points for their audiences who contribute to national affinity. Drawing on recent scholarship on the politics and pleasures of reality television, Punathambekar (2010) studies a series of events surrounding the third season of *Indian Idol* to explore how reality television, situated to the changing landscape of Indian television, has enabled new modes of cultural and political expression. In their consideration of the *Super Girls' Voice*'s audience

(a Chinese counterpart of *The American Idol*), Cui and Lee (2010) focus on the issue of whether the reality show has altered the power relationship between the media and the audience. Most of their focus group discussants enjoyed watching the 'super girls' for their ordinariness, but still derived satisfaction from seeing how these ordinary girls became extraordinary through the reestablishment of the media/ordinary boundary.

One of the major trends of the last decade has been the 'regionalization' of media productions and reception within the multicountry markets linked by geography, language, and culture. For instance, Japanese pop cultures and Korean TV dramas have been startlingly successful in the East Asian region since the late 1990s. The regional media flows open up new possibilities to study non-Western audiences in terms of their perceptions of colonial–postcolonial relationships, gender subjectivity constructions, and nationalist responses to transnational media culture exchange. Lin and Tong (2008) conducted a comparative study of the viewing practices of female fans in Hong Kong and Singapore. Based on in-depth interviews with the fan groups, they found that these female audiences are adept in using Korean dramas to construct what they see as their distinctive 'Asian' modern femininities. While both groups appreciated the hybridization of traditional values and modern images in Korean dramas, the female viewers in Singapore seemed to be more inclined toward traditional values and Confucian ideals of femininities than the Hong Kong viewers. Through interviews with middle-aged female fans in Japan, Mori (2008) found that the penetration of Korean TV dramas into actual Japanese family life has political potential for understanding and reconstructing Korea–Japan relationship in new ways. These studies demonstrate the emergence of regional media culture and offer new conceptual insights into global audience studies, which cannot be ascertained through previous US-centric analyses.

Besides the global flow of media production and consumption, audience studies can also be used to examine how migrants, multinational citizens, and other cosmopolitans use the media to negotiate their identities and transnational connections. Gillespie (2006) started a collaborative ethnographic study of the news-viewing practices among multilingual households in the United Kingdom. Interviewees watched the attacks of September 11 on multiple news channels and in a variety of languages, then discussed with researchers their everyday media practices. Given the perceived bias in Western reporting, these transnational viewers actively sought alternative news sources through the use of satellite television and the Internet. This study contributes to the scholarship on the emergence of transnational audiences, publics, and identities.

There is a difference in emphasis, however, between the transnational studies of traditional media (e.g., TV programs and videos) and the research centered on the use of new media (e.g., mobile phones and the Internet). As Lewis and Hirano (2001) found in their study of Thai-Australia families, watching rented Thai videos serves as a site of escapism for Thai brides who are culturally and socially isolated. Although their use of ethnic video drama helps Thai brides to cope with their nostalgic sentiments, it does not change the marginalized social status that they often enjoy in their host country. In contrast, a number of scholars (e.g., Hiller and Franz, 2004; Chan, 2010) who studied how migrants use new communication technologies, especially the use of Internet, suggest that migrant groups benefit concretely from their online activities in terms of cultivating social ties in both home and host countries, and forming cyber-communities that facilitate their social adaptation to the new environment while maintaining strong attachments to the homeland. These studies have illustrated the value of studying audiences or the users in the new media context as a key way to understand the transnational identities and lived realities of diasporas.

As noted in previous examples, cross-national research proves to be one of the most fruitful research approaches in transnational media studies. Based on in-depth interviews conducted in 2001 and 2004, Elias (2008) studied how Russian-speaking returnees from the former Soviet Union use electronic and print media in Israel and Germany. A parallel comparison of returnees in Israel and Germany afforded an interesting case to examine the immigrants' media consumptions in different structural and cultural contexts. The findings showed that these immigrant groups used the media in very different ways. Characterized by assimilative media consumption, returning immigrants in Germany limited themselves nearly exclusively to consumption of German-language media. However, German-speaking media did not guarantee 'a free ticket into German society' (p. 138). These immigrants felt alienated and isolated from German culture even when speaking German. In contrast, Russian-speaking Jews seek out various forms of Russian-speaking media in Israel. Both newcomers (1–3 years in residence) and old-timers (5 years in residence), who get information through Russian-speaking media, however, do feel at home in Israel. This study points out the importance of political, ideological, and cultural factors, which condition both media consumption of the immigrants and their integration into the host society. While traditional ethnography focuses on particular ethnic groups in a specific geographic place, a revised ethnographic approach targeting international audiences needs to draw out the wide connections between local experience and the global context in which their cultural identity is located.

Directions for Future Research

Regarding television audiences specifically, the emergence of cable technology at the end of the network era fundamentally altered the ways in which content becomes socially important. In describing the shift from the multichannel transition period, which began in the 1980s, to the postnetwork era in the early 2000s, Lotz (2007) notes that the emergence of so many new networks and niche channels fundamentally changed the economics of the television industry. Also, rather than delivering large audiences to advertisers within this new environment, producers, like advertiser-supported cable networks, can afford to create content that will only be watched by 1% of the available audience (Lotz, 2007: p. 37). As a consequence of these economic and cultural realities, postnetwork television

differs from the programming of the network era in that the cultural relevance of any content ceases to be a direct function of audience size, and producers are no longer limited to creating content that appeals to 'a multiplicity of social types at once' (Gitlin, 1982: p. 248).

With such changes, the medium has become increasingly legitimate as a cultural form with the production of targeted content appealing to high-income, educated niche audiences. A recent Harvard course centered on HBO's The Wire (Chaddha and Wilson, 2010) confirms Lotz's assertion that only in the context of television's postnetwork era can a particular content be affirmed by "hierarchies of artistic taste and social importance" and become "imbued with what Pierre Bourdieu terms 'cultural capital'" (Bourdieu, 1984; quoted in Lotz, 2007: p. 40). According to Newman and Levine (2012), however, the cultural legitimation of quality television content relies on the same imbalanced binaries that are associated with the medium's historical degradation. As a result, television is now bifurcated. Content reminiscent of network era programming becomes 'bad' television in the postnetwork era because of its association with the passive, 'feminized' viewing experiences of mass audiences; while television shows like *The Sopranos* and *The Wire* become 'good' television because of their association with the active, 'masculine' viewing experiences of elite niche audiences. In contrast with previous research examining the relationship between social class and television audiences (Press, 1991; Morley, 1980, 1988; Seiter, 1999), however, the relationship between social class and postnetwork audiences remains largely unexplored.

Furthermore, as audience researchers we must also acknowledge that the television landscape is changing, blurring the lines between producer and consumer (Meyrowitz, 2010). One of the fastest growing sectors of participatory television is the genre of 'reality television,' a programmatic landscape that purports unscripted, real-life glances at the lives of 'ordinary' people (Holmes and Jermyn, 2004). To date, most scholarship emphasizes the way reality television reinforces class differences and reveals the role television continues to play in constructing hegemonic discourse (Lizardo, 2010; Grindstaff, 2002; Couldry, 2011; Andrejevic, 2011). More attention must be paid to *biopic* reality television, formats that mimic documentaries. Since biopic narratives are situated in identifiable communities, they provide the opportunity for understanding how *indirect participants* negotiate their cultural and class position in relation to reality television. These 'integrated audiences' have friends, relatives, and members of their community featured on national television, but still act as an audience, *consuming* the final product (Tripodi forthcoming).

Conclusion

With the changing media environment and changing media genres and formats, the shape, structure, and even the very definition of the media 'audience' keeps changing in ways that acknowledge the more active and interactive roles that audiences play in the new media environment. As Barker and Mathijs (2012) find in a multimethod research project spanning a dozen countries and generating 25 000 responses, "cultural product such as films are not message-vehicles, to be assessed for their lesser or greater 'effect,' but complexly organized bodies of meaning, which draw on and react back onto their constitutive culture" (676). They also note the increasing importance of ancillary texts as "news, reviews, gossip, leaks, publicity, posters, merchandising, etc., work in complicated ways, and with different groups of people, to steer, influence, or create emergent frames for receiving and affiliating with as a film such as *Lord of the Rings*" (679). Nonetheless, the term 'audience' itself is progressively less used as scholars confront the issue of how to study media influence as media become more fragmented and more interactive.

The 'mass' sense in which we thought of the media audience in the first decades of our field has now evolved into a sense that most audiences are 'niche' audiences of various sorts, and that all audiences are active to some degree, though some are more active, and interactive, than others. This necessarily changes, and is continually changing, the sorts of questions it's important for audience researchers to ask; the design of audience research studies; the way we think about the relationships between production, reception, activity, and passivity in the context of media audience study, and the way we think about the nature of media influence itself, and how we should conceptualize this. The study of media audiences, however, continues to be a central and important part of media research more generally, and will continue to be so even as the media environment, media genres, and the relationship between media production and reception continue to evolve.

This article is a replacement of the previous edition article by G.J. Brown, volume 2, pp. 942–946, © 2001, Elsevier Ltd.

Abstract

Listeners have to make sense of a complex acoustic world containing overlapping sound sources that must be organized into individual auditory objects. Computational auditory scene analysis concerns the use of algorithms inspired by human sound perception whose aim is to extract properties of constituent sound sources in a complex mixture. Starting with representations based on models of how sound is processed in the peripheral auditory system, typical computational auditory scene analysis techniques function by decomposing the mixture into components followed by selective recomposition into groups of components that appear to emanate from a single source. Grouping processes can be informed by information in the signal itself or by the use of prior statistical models of sound sources. This article outlines some of the principal signal decompositions used in models of auditory grouping and goes on to describe a decoder that combines both signal- and model-driven grouping processes.

Introduction

We live in an acoustically cluttered world and are often forced to pick out the sound source of interest from the mixture reaching our ears. Computational auditory scene analysis (CASA) is the branch of machine perception that attempts to extract information about the location, identity, and content of individual acoustic sources in a mixture (Lyon, 1983; Brown and Cooke, 1994; Ellis, 1999; Wang and Brown, 2006). CASA algorithms differ from other engineering approaches to source separation by being both inspired and constrained by human perceptual organization of sound. In practice, this means that CASA algorithms operate with signals from one or, at most, two microphones; employ a first stage of signal analysis using a computational model of the peripheral auditory system; and embody auditory grouping processes informed by auditory scene analysis.

CASA grew in part from investigations of the perceptual organization of sound in listeners (Bregman, 1990; Darwin, 1981), although early research in the nascent field of CASA (e.g., Cooke, 1993) was also influenced by computer vision, especially the work of Marr (1982). Computational techniques in hearing and vision distinguish between bottom-up 'signal-driven' processes that extract information from sensor data, and top-down 'model-driven' processes that use prior knowledge of objects to interpret features derived from the signal. However, there are important differences between the two modalities that are reflected in computational approaches in each field. While vision systems routinely handle large numbers of spatially separated objects, the number of individual acoustic sources of interest is usually far smaller, but the separation problem is more challenging since information about each source is overlapped in both time and frequency. Likewise, while attentional-controlled searches for salient objects in the spatial dimension comprise a key aspect of computer vision systems, temporal processing plays a more important role in accessing information in computational audition (e.g., following a conversation in the presence of other voices or tracking a single instrument in a polyphonic composition).

As described in the sections of this article, CASA algorithms operate by first decomposing the incoming sound mixture in order to transform the signal into domains where the constituent sources are more easily separable, then selectively recombining signal elements, often based on auditory grouping principles, where there is evidence that the elements originated from the same acoustic source.

Signal Decomposition

The decomposition stage converts one or two one-dimensional microphone signals into one or more two- or three-dimensional representations of sound, whose purpose is to more clearly reveal features of the individual acoustic sources such as periodicity or spatial location, thereby facilitating sound separation. Typically, decomposition proceeds by converting each microphone signal into an 'auditory spectrogram,' a representation of auditory nerve activity as a function of frequency and time. Example auditory spectrograms are shown in **Figure 1** for a female talker, a male talker, and a mixture of the two. Each image results from passing the signal through a bank of 100 bandpass filters whose shapes and center frequencies are first approximations to human auditory filter shapes derived from psychophysical studies (Glasberg and Moore, 1990). The temporal envelope in each frequency band has been extracted, smoothed, logarithmically compressed, and converted to a grayscale, in which darker areas correspond to more energetic sound components.

While the auditory spectrogram is primal in documenting the relative energy balance of the constituent sources in a mixture at each time and frequency point, fine timing information is lost in its construction, and other transformations are typically applied to the signal at the high temporal resolution output of each modeled auditory nerve fiber. The two most common transformations are based on auto- and cross-correlation, inspired by early physiological models of Licklider (1951) and Jeffress (1948), respectively. The 'correlogram' representation, shown in **Figure 2(a)**, is the

Figure 1 Auditory spectrograms for utterances by a female (top) and male (middle) talker and for their equal-energy mix (bottom).

collection of autocorrelation functions of auditory filter outputs, applied independently in each frequency band. In principle, the correlogram is a three-dimensional representation of sound, with dimensions of cochleotopic frequency, autocorrelation delay ('lag'), and time, but in practice it is computed on short overlapping segments of the signal. Autocorrelation enhances periodicities in each frequency region, and, as explained in this article, it is the across-frequency grouping of common periodicities that can be used to separate sound sources at those time instants where one or both are periodic, as is the case for speech signals at moments where the vocal cords are active, or for plucked instruments.

In a similar manner, pairs of microphone signals can be cross-correlated to highlight the delays at which the two signals are most similar, based on interaural time difference cues to the source azimuth. More recently, for sensors mounted on head simulators, CASA models (e.g., May et al., 2011) have attempted to reinforce time difference cues in the cross-correlogram with level difference estimates motivated by the observation that energy received at the sensor on the opposite side of the head to the source is substantially attenuated relative to that of the closest microphone. Other low-level signal transformations applied in CASA systems include the extraction of temporal envelope modulations, which can encode the fundamental frequency of periodic sources and other modulation components (e.g., Hu and Wang, 2004), as well as source onset and offset enhancement (e.g., Brown and Cooke, 1994).

Grouping: Recovering Individual Sound Sources by Selective Recombination

Having transformed the acoustic mixture into representations in which evidence for each individual source is more salient, the remaining task for CASA algorithms is to determine which elements belong together in order to reconstruct one or more sources. Early algorithms focused exclusively on the application of auditory grouping principles based on information in the signal itself. More recent approaches have incorporated prior knowledge of sound sources, often embodied in probabilistic models. We consider each in turn.

Signal-Driven Grouping

Figure 1 exposes a multiplicity of cues that might be used to recombine signal elements into source descriptions without prior knowledge of the individual sources. Considering the lower panel which depicts the mixture of male and female

Figure 2 Using pitch cues to separate a two-talker mixture. (a) Correlogram; (b) summary correlograms for the mixture (top) and formed from spectral components dominated by the male (middle) and female (bottom) voice; and (c) sequential grouping of multiple pitch tracks. From top to bottom: auditory spectrogram of the mixture; ground truth for regions dominated by the female (black) and male (gray) voice; pitch estimates derived from the correlogram, with red dots indicating the stronger source and blue crosses the weaker source; pitch estimates (red) produced by the multipitch tracking algorithm, with ground truth in blue; and regions corresponding to estimated pitches. Adapted from Figures 6 and 10 of Ma, N., Green, P., Barker, J., Coy, A., 2007. Exploiting correlogram structure for robust speech recognition with multiple speech sources. Speech Communication 49, 874–891.

voices, it is evident that each voice can be associated with a number of time-varying partials that are harmonics (integer multiples) of a common fundamental frequency. These components, apparent in the low- and midfrequency regions, share a common onset time, maintain harmonicity as they change smoothly over time, and to a large extent possess simultaneous offsets. In the mid- and high-frequency regions, we see evidence of frequency components enhanced by the resonant cavities of the vocal tract. Again, these share common onsets and offsets with the harmonic partials and change smoothly over time. A closer look reveals periodic vertical structures, which are most evident around 0.9 s for the male voice. These correspond to amplitude modulations caused by the interaction of more than one harmonic component in a single auditory filter, and for midfrequencies the modulation period is equivalent to the harmonic separation (i.e., the fundamental frequency). In principle, then, periodically excited portions of a sound source such as speech can be recombined on the basis of a common fundamental frequency along with continuity constraints and onset–offset synchrony.

A representative signal-driven grouping algorithm based on fundamental frequency (Ma et al., 2007) is depicted in Figure 2. Panel A shows the correlogram for a single frame of a mixed male and female talker signal. The correlogram represents the periodic structure of the signal in each frequency region in a small time interval. The main value of the underlying autocorrelation function comes from its property of preserving periodicities in the input signal while removing phase information. In response to a periodic signal, each frequency region of the correlogram contains peaks at delays corresponding to multiples of the frequency of dominant components in that frequency region. So, for a harmonic series, low-frequency channels will produce a peak at the frequency of the lowest component, while progressively higher channels will possess peaks at the frequency of the nearest component and at integer multiples of that frequency. For example, in response to a voice with a fundamental frequency of f Hz, peaks will be present at delays of $1/f$ s, $2/f$ s, and so on in the low-frequency region; at delays of $1/2f$ s, $2/2f$ s, and so on in a slightly higher frequency region; and at lags of $1/3f$ s, $2/3f$ s, $3/3f$ s, and so on for the next frequency region. Critically, note that each frequency region contains a correlogram peak at a delay of $1/f$ s. It is this coincidence that makes the correlogram a powerful representation for discovering fundamental frequencies of constituents of a mixture. The coincident delays can be seen as vertical structures in Figure 2(a). In order to extract dominant fundamentals, it is usual to sum

the correlogram across frequency channels, resulting in a summary correlogram as depicted at the top of Figure 2(b). The largest peak corresponds to the female voice at a lag of around 4 ms (250 Hz), while other peaks can be seen at around 8, 9, and 12 ms. In principle, it is possible to identify which frequency regions contributed to each peak, and thereby group together those that appear to come from the same source. Unfortunately, due to the presence of large numbers of autocorrelation peaks in the midfrequencies, it is not feasible in practice to use the correlogram directly in this way to perform source separation. One solution, adopted by Ma et al. (2007), is to sharpen the correlogram using Gabor cosine operators in what is essentially a matched filter operation taking advantage of the local 'pyramidal' structure of the correlogram. This results in a less ambiguous summary correlogram, but peaks in the summary are still not guaranteed to correspond to the fundamental frequency of one of the constituent sources, as shown by the estimates derived in this way in the third panel of Figure 2(c). Consequently, a multipitch tracking process is normally used to exploit temporal continuity constraints in order to resolve ambiguous local pitch estimates.

Grouping using intrinsic signal properties such as common fundamentals can go some way to reconstructing an individual sound source. However, there are limits as to what the signal-driven approach can accomplish. One specific issue concerns those parts of the signal that are not periodically excited, such as the voiceless consonants /s/, /th/, and /f/ in 'set', 'three,' and 'four' in Figure 1. Grouping of voiced and voiceless elements has received relatively little attention in CASA (but see Hu and Wang, 2011), but it can in principle make use of the onset–offset synchronies that result from an alternation of voiced and voiceless elements, or interaural time and level differences that signal a common source azimuth (Harding et al., 2006).

Pure Model-Driven Grouping

Individual acoustic sources are often highly structured, containing regularities that can be captured by discrete or probabilistic models. For instance, in the case of speech, constraints exist at every level, from articulatory limitations (e.g., vocal-tract size or vocal fold vibration rate) through to linguistic determinants of lexical, grammatical, and semantic possibilities. Similar considerations apply to musical instruments and animal vocalizations. Even less-structured sounds, including those originating from the combination of multiple sources (e.g., babble, traffic, leaves rustling, and waves crashing), exhibit patterning in their spectral profile or temporal modulations. In all these cases, source models can be learned from data, and more recent CASA systems have shown how this kind of prior knowledge can be used to separate a mixture into its individual components. The key idea is to combine statistical models for each source believed to be present at each instant in the mixture in an attempt to explain the acoustic observations. In this way, sources are separated essentially as a by-product of recognition. The original scheme, proposed by Varga and Moore (1990), has since been extended to cope with the computationally complex process of evaluating all possible combinations of a large number of source models. Source model combination can be extremely effective. Indeed, algorithms have been demonstrated that outperform human listeners in limited-domain tasks such as the recognition of speech from one talker in the presence of a competing talker (Rennie et al., 2010).

Identifying a Target Source in an Unknown Background

The fundamental problem faced by listeners is to extract information from a single target sound source in the face of other sounds, whose composition (e.g., type and number) may vary over time. Pure model-driven grouping fares less well in situations where the number of active sources has to be estimated, and also requires statistical models at some level of structural detail for all sources present. A source separation system aimed at tracking a single target in an arbitrary background was proposed by Barker et al. (2005). The system makes use of both signal-driven and source model-driven grouping, and is based on the notion of 'glimpses,' motivated by energetic masking considerations in the auditory periphery. As a consequence of loglike amplitude compression in the cochlea, auditory nerve activity in each frequency region is dominated by the most energetic source active at that instant to such an extent that weaker sound sources make almost no impact on activity unless they are within a few decibels of the stronger source. Because many sounds exhibit sparse concentrations of energy across time and frequency, the likelihood of any pair of sources contributing similar energies in any spectro-temporal location is quite low. In other words, while sources are acoustically transparent, they are better characterized as opaque after encoding in the auditory periphery. The mixture shown in Figure 1 illustrates the opacity approximation. Locally, each part of the auditory spectrogram is nearly identical to the corresponding region of the auditory spectrogram for one of the constituent talkers. Some interactions between the sources are visible (e.g., in the low-frequency region at around 0.6 s), but most of the spectro-temporal plane provides a relatively undistorted view of one or other sources.

The glimpsing idea is further illustrated in the upper panel of Figure 3, which uses a form of color coding to denote spectro-temporal regions in a mixture of two talkers that is dominated by one or the other talker. Each compact region of a single color is a potential glimpse of one source. Of course, glimpses do not arrive at the auditory system with a convenient color code, and the computational task is akin to taking two or more jigsaws, throwing away some large fraction of the pieces of each, and attempting to identify the original pictures. Recast in this manner, the focus of glimpse-based CASA is on the twin problems of glimpse detection and integration. Detection is well suited to signal-driven grouping. Potential glimpses of sufficient spectro-temporal extent typically contain cues based on features such as periodicity or onset synchrony which allows them to be constructed using the kinds of signal-driven grouping algorithms outlined in this article. Glimpse detection avoids the need for extensive grouping of elements, especially across time, and thereby greatly simplifies the CASA problem.

The glimpse integration stage requires probabilistic models for the target sound source. For speech, these would typically be hidden Markov models for phonemes, words, or some other unit. The goal, shown in the panel in Figure 3, is to find both

Figure 3 Upper: An auditory spectrogram of a two-talker mix represented by a hue saturation value encoding. The value corresponds to the log energy of the mix, as for conventional auditory spectrograms, while the hue and saturation values are derived from the log of the local target-to-masker energy ratio. Positive values map on to green, while negative map to blue. The magnitude of the log energy ratio maps on to the saturation term. In this way, regions where one source is clearly dominant show up as a single well-saturated hue, while regions where the energy ratio of the two sources is similar possess an intermediate unsaturated hue. Lower left: An illustration of the decoding algorithm applied to the first three glimpses. Lower right: Definition of the glimpse decoder for word models.

the most likely word sequence and the set of glimpses that explain the acoustic observations. Decoders of this type rely on missing data techniques (Cooke et al., 2001; see also Seltzer et al., 2004) to permit models to be evaluated against the partial information contained in glimpses.

A brute force approach to glimpse integration would require the evaluation of all possible subsets of glimpses against all permissible model sequences, something that is clearly infeasible. However, a computationally tractable algorithm for glimpse integration is available, as illustrated in Figure 3. Consider first the way that a conventional decoder for sources such as speech operates. At each moment in time, the decoder maintains a very large number of alternative partial interpretations of the data (e.g., incomplete phrases) up to that point, each of which has an associated likelihood. At the next time instant, a new acoustic observation becomes available and is used to update all existing interpretations. Finally, on reaching the end of the utterance, the most likely interpretation is chosen as the recognized result. The glimpse decoder operates in a similar fashion up to the point at which a new glimpse is encountered. At this point, each ongoing hypothesis is cloned. In subsequent time instants, one hypothesis is evaluated by including the glimpse in its interpretation, while its cloned counterpart excludes it. When the glimpse ends, all pairs of cloned hypotheses are compared and the most likely path of the pair is retained, under the assumption that later-arriving glimpses will not affect the earlier interpretation. Compared to a conventional single-source decoder, the complexity of the glimpse decoder is increased by a factor that in the worst case is 2 to the power of the largest number of temporally overlapping glimpses encountered. This number depends in turn on the power of signal-driven grouping in detecting glimpses. In this way, the decoder trades off signal and model-driven grouping: the more successful the signal-driven grouping stage, the fewer alternatives are presented to the model-driven stage.

Applications, Evaluations, and Future Challenges

The ability to describe the content of complex acoustic environments will find widespread application in many fields, including human–computer interfaces, health, security, entertainment, and robotics. Key beneficiaries of general-purpose CASA will be hearing-impaired individuals, for whom selective enhancement of sources of interest will be possible. Other applications include robust automatic speech recognition for everyday (i.e., potential noisy) conditions, remote audio surveillance, automated music analysis, transcription, and repair, as well as providing audio descriptions and audio awareness for robots.

Much effort in CASA to date has been dedicated to tackling the 'cocktail party problem,' which involves separating or recognizing a voice of interest in a background of one or more distracting voices. This formed the challenge problem for the first global evaluation of speech separation and recognition systems, which took place in 2006 (SSC website). While speech separation in the cocktail party task is an important goal, and one that is particularly relevant for hearing-impaired listeners, it is a largely artificial problem. Realistic sound environments have additional complications such as the presence of sound sources whose type and number vary over time. This scenario forms the basis for current evaluations (CHIME website).

Future systems can be expected to handle moving sources. To counteract these and other dynamic elements of auditory

scenes, CASA systems may well utilize active sensors to simplify the tracking of moving targets while attenuating the contribution of competitors. More sophisticated scenarios demand models of auditory attention capable of focusing on sources of interest while responding to relevant novel events. Richer characterizations of the auditory scene will be possible by using algorithms that construct more complete spatial descriptions than is currently the case, going beyond azimuth estimates to include elevation and distance. An additional challenge is to develop more robust scene analysis algorithms that are capable of handling and indeed exploiting reverberant energy and other convolutional distortions. Finally, it is likely that auditory and visual scene analyses will be more closely integrated in future in order to exploit the advantages of each modality.

Abstract

Various chronologies for the arrival of modern humans in Australia and New Guinea are discussed, together with a consideration of possible routes of entry. The archaeological evidence from the New Guinea Highlands and the islands of Melanesia is reviewed. After a general discussion of human colonization of Pleistocene Australia, some of the key sites in two contrasting environments – the arid zone and Tasmania – are compared.

Dating the Arrival of Humans

Although today Australia, Tasmania, and New Guinea comprise three separate landmasses, during times of lowered sea levels in the late Pleistocene they formed a single continent called *Sahul*. There is general consensus that Sahul's first human colonizers were both anatomically and behaviorally modern humans; indeed the necessary crossing of a minimum water barrier of *c.* 90 km to reach New Guinea or Australia in the late Pleistocene constitutes one measure of that modernity (Davidson and Noble, 1992).

Beyond that, there is little consensus for the date of earliest arrival (O'Connell and Allen, 2004). The oldest claims, in the 100–200 ka (thousands of years) range, all depend upon ecological evidence – usually charcoal counts in pollen cores interpreted as anthropogenic rather than natural fires – and are claimed in both the north and south of the Pleistocene continent, as well as Eastern Indonesia. The second group of claims consists of analyses of mtDNA diversity which put humans in Sahul *c.* 70–100 ka. A third group of claims associate direct archaeological evidence with uranium series, luminescence, and electron spin resonance dates in the 50–70 ka range. The fourth category includes those sites which form the beginning of a continuous sequence of occupation in the Pleistocene continent which may extend to 45–47 ka sidereal years ago. Certainly by *c.* 40 ka all the major ecological zones of Sahul and nearby islands such as New Britain and New Ireland – and perhaps even the main Solomon Islands chain – had been colonized by humans.

Claims in the first very ancient group have little credibility because they lack direct artefactual evidence and because it is difficult to accept on the basis of current global evidence that humans in Sahul before 100 ka could have been anatomically and behaviorally modern. Distinctly premodern *Homo floresiensis* probably reached the island of Flores during this period or even earlier but apparently moved no further east, probably because its original movement across the water barrier known as Wallace's Line was accidental (Morwood and Jungers, 2009). Wallace's Line marks the distributional divide between Old World placental mammals and Australian/Sahulian marsupials, but a few now-extinct Old World mammals such as Stegadon elephants also made the short crossing to Flores then advanced no further toward Sahul. Further afield, pre-sapiens humans also reached the Mediterranean island of Crete at least 110 ka, but only had to cross about 30 km of water, not the 90 km needed to reach Sahul (Strasser et al., 2011).

Three specifically archaeological claims put humans in Australia before or at 50 ka. The western New South Wales burial known as Mungo 3 has been redated to *c.* 56–68 ka using uranium series and electron spin resonance techniques on the skeletal elements and OSL to date the surrounding deposits (Bowler et al., 2003). This is particularly dramatic because the Mungo 3 human was ritually buried and covered in red ocher. Such burial is seen as a marker of modern behavior, and if as old as this, would be the oldest unambiguous ritual burial of *Homo sapiens* presently known anywhere. The second claim is for two rockshelter sites in the Northern Territory, Nauwalabila and Malakunanja, where the deepest stone artifacts are associated with TL and OSL dates having central tendencies between 50 ka and 60 ka (Roberts et al., 1994). Here critics question the *in situ* nature of the deepest artifacts being dated rather than the dating techniques themselves (*see* Chronology, Stratigraphy, and Dating Methods in Archaeology). Similar criticisms have been leveled at the third example, the recent AMS dating of the Devil's Lair cave in southwest Western Australia to *c.* 48–50 ka (Turney et al., 2001), where the lowest levels of the site which produced this date are water-scoured and contain only a few stone flakes, some not clearly of human manufacture.

Defenders of the longer chronologies criticize the shorter chronology on the grounds that the great majority of dates are based on older radiocarbon dating which was unreliable for ages much over 40 ka, so that this age for earliest arrival might easily be a product of the technique (O'Connor and Chappell, 2003). However, modern radiocarbon techniques now produce accurate dates up to 45 ka and have done so regularly in Australia for nonarchaeological samples, but only on relatively few occasions for archaeological sites.

The resolution of this debate is needed to understand the rate at which Sahul was colonized, and the adaptive strategies used to occupy a wide range of new environments. Equally important are the implications of this debate for understanding the spread of modern humans elsewhere in the world, since behaviorally modern humans are unknown before *c.* 50 ka anywhere in Eurasia (Barker et al., 2007; Dennell and Petraglia, 2012; Kaifu and Fujita, 2012).

Routes of Entry

The Sunda shelf of Southeast Asia is separated from the Sahul shelf of Australia, Tasmania, and New Guinea, and this break forms a significant biogeographical boundary first recognized by Alfred Russell Wallace. As noted above, Wallace's Line separates an Asian fauna which includes primates, carnivores, elephants, and ungulates from the marsupial fauna of Australia, Tasmania, and New Guinea. However, the widespread elements of Asian flora in Indonesia, New Guinea, and into northern Australia indicate that this boundary still permitted the natural transfer of this flora.

Two routes of entry from Southeast Asia seem possible, the first and more northern route through the Indonesian Moluccan archipelago to New Guinea, and a second more southern route along the Flores chain to Timor and then to northern Australia (Allen and O'Connell, 2008; Birdsell, 1977). Any of the subroutes which might form the northern route had two sailing advantages which the southern route lacked – intervisibility between departure point and target landfall on all legs and the ability to return to the departure point on existing winds and currents. Sea craft could journey blind from Timor to Australia on the summer monsoon, but not return. Interestingly, altered heights of islands because of sea level fluctuations had no appreciable effect on either intervisibility or distance between landfalls.

The earliest coastal site in New Guinea is at its extreme eastern end, emphasizing the absence of systematic archaeological exploration of the western half of the island. This site, an open site on uplifted coralline terraces on the Huon Peninsula, has yielded dates of *c.* 40 ka or a little older for large tanged and waisted flaked axes which must have been hafted.

New Guinea Highlands

New Guinea is dominated by a steep central cordillera rising to 4000 m asl in places. Because of rainfall patterns and cloud cover, Pleistocene colonists likely settled the series of intermontane valleys ranging between 1200 and 2400 m. Currently, the oldest dates for humans in the highlands are *c.* 45 ka, the lack of any time lag from the coast indicating how adaptable early colonists must have been to settle this remote region so quickly. This date is for the recently re-excavated site of Kosipe, located at 2000 m in the Ivane Valley, where stone tools, hearths, and plant and animal remains were found (Summerhayes et al., 2010). The animal bone cannot be identified but the floral remains indicate the exploitation of local pandanus as well as yams from lower altitudes. The excavators think the site was only visited during this period and not permanently inhabited. The subsistence patterns reflected in other excavated sites like the Nombe rockshelter reflect a strategy of hunting and collecting across a range of high-altitude zones. While forests and grasslands contained mainly small game, Pleistocene New Guinea was also home to a small number of large mammals, all now extinct. At Nombe, four species – all forest browsers – occur between *c.* 25 ka and *c.* 14 ka, but it is uncertain whether they were human prey. The general paucity of game animals in New Guinea is, however, offset by the huge array of plants, of which more than 200 are used for food. While little direct evidence exists for the development of plant processing and plant storage, it is likely that these processes developed from the beginning. The Huon-type axes also occur at Nombe, Kosipe, and other early sites, where they have been identified as tools used to thin forest patches by trimming and ring-barking so as to promote the growth of useful plants. The burning of forests at this time is reflected in the pollen records and supports this interpretation.

If accurate, these data suggest a long evolution of plant management which culminates in a distinctive highlands agriculture at 9–6 ka at Kuk in the Wahgi Valley (Denham, 2006). Here evolutionary stages of garden technology have been identified, including hydraulic practices involving both drainage and irrigation. The most recent phases reflect the familiar root crop/arboriculture/pig-husbandry systems present in the highlands today. Pigs, not indigenous to New Guinea, appear in the archaeological record 5–6 ka with some claims back to 10 ka (Denham, 2006).

Island Melanesia Before Lapita

Moving into the nearer islands of Melanesia required adapting to the simplified terrestrial ecology of an oceanic world. The initial colonists adopted strategies which compensated for this reduced range of edible plants and terrestrial animals through high mobility across large territories. This, in turn, depended on safe, if simple, watercraft. Initially it appears such craft took people to scattered resources, but over time, as populations and specialized resource knowledge increased, moving resources to people increasingly replaced the first strategy.

Because of tectonic uplift and deep submarine contours along the north coast of New Ireland, Pleistocene sites now normally flooded by later rising seas have been preserved (O'Connell and Allen, 2007; Leavesley, 2006). The oldest known of these, Buang Merebak, recently redated to 40–41 ka, and Matenkupkum (*c.* 35 ka) are about 140 km apart, and both contain marine shell middens which are very similar. Both contain marine fish bones indicating some form of fishing at this age, and both reflect strategies of shellfish collecting and processing the shells for food and tools. People also moved inland, quarrying chert outcrops near Yombon in New Britain at *c.* 36 ka. At Kilu Cave in the northern Solomons, stone tools dated between 29 and 20 ka carry residues of *Colocasia* and *Alocasia* taro, in quantities sufficient to suggest that successful selection had already taken place for starch-rich tubers.

Getting to Kilu required a sea journey about twice that of any prior necessary crossing between mainland Southeast Asia and the Bismarck Archipelago, a voyage without the aid of two-way intervisibility. But by 21 ka people had reached the Admiralties Group, a voyage of over 200 km which required that 60–90 km be traversed totally out of the sight of any land; this is the earliest known example of true seafaring anywhere.

By 20 ka, moving resources to people is reflected in New Ireland in the appearance of obsidian from a New Britain source 300–350 km distant and the introduction of *Phalanger orientalis*, a marsupial which became an important food source. It is the first of a series of animal translocations in the region and flags the possibility that useful plants and nut-bearing trees were also moved about well before the end of the Pleistocene.

A reduction in cave use in the region during the early Holocene raises the question of whether these islanders were more dependent on cultivated plants than previously. While

the evidence is piecemeal, gradual economic intensification is reflected in aspects of the archaeology such as intensive and extensive trade in obsidian, plant residues on tools, domesticated and transported nut remains in sites, elaborate stemmed and hafted obsidian and chert tools, stone and shell ground axes, open-site settlement patterns, and expansion onto smaller offshore islands, all of which seemingly demand more substantial food production systems than those provided solely by hunting and gathering.

Maritime trading systems developed in part on Pleistocene foundations elaborated during the later Holocene, as horticulture underwrote village development both in the near islands and around the New Guinea coast (Pavlides, 2006). The growth of these systems, particularly after the spread of Lapita-introduced pottery technology, has been a major research concern of archaeologists in the region (*see* Pacific Islands, Archaeology of).

Australia

Regardless of where first landfall occurred, the move south through Sahul was into environments more foreign in their floras and faunas and in increasing contrast to presumed tropical humid homelands. Although more than 160 Pleistocene age sites are known in the region, they occupy a diverse range of environments and are frequently great distances apart, such that no neat synthesis of past human behaviors is yet possible. A few short generalizations will provide some background (Hiscock, 2008; O'Connell and Allen, 2007). (1) With some glaring exceptions, such as edge–ground axes in Arnhem Land at *c.* 20 ka, Pleistocene flaked stone tools across Australia are mostly amorphous, showing little of the elaboration which characterizes the Upper Palaeolithic in Europe or the Later Stone Age in Africa. (2) A host of larger marsupials, collectively dubbed megafauna, appear to have become extinct around the time of human arrival, although the dating of the extinction event(s) is poor. While it is difficult not to implicate humans in this extinction, the processes are unclear. Direct extinction by hunting appears unlikely, given the range of species, the size of the continent and its varieties of environments, the presumed low numbers of humans, and the conspicuous absence of kill sites. Many commentators appeal to less direct effects, particularly habitat modification by the human use of fire, but not even this effect is universally endorsed. Arguments of climate change are still advanced to counter human involvement, but these are also widely criticized. (3) Various sorts of small blade-tools and points which first appeared in low numbers in different parts of the continent from *c.* 7 ka dramatically increased in popularity from *c.* 4 ka throughout Australia, but not in Tasmania, which had been cut off from Sahul by rising postglacial sea levels some 13 ka (Hiscock, 2006). (4) Despite the example of New Guinea to the north, which remained attached to Australia until cut off by rising postglacial seas *c.* 7 ka, Aboriginal people did not adopt or develop agriculture, remaining a continent of hunter–gatherers until European arrival. Even so, the successful colonization of even extremely marginal areas of the continent reflects the adaptability of these people, while the widely documented development of art and engraving on rocks and cave walls, now demonstrated from earliest arrival, reflects an intellectuality and social awareness among aborigines previously only documented ethnographically.

The Arid Zone

The arid zone occupies an area of *c.* 5 million square km – about 70% of Australia's land surface – and during the Pleistocene this area was even larger owing to glacial aridity. In this region, occupation and movement has always been constrained by the distribution of food and water (Hiscock, 2008; O'Connell and Allen, 2007). Areas of relatively high relief, the ranges of the central desert and the Kimberly and the Pilbara in particular, concentrate run-off in stream channels and waterholes; similarly, riverine floodplains contain perennial and seasonal streams which contain surface water in some seasons and store accessible subsurface reserves. The riverine floodplains, particularly those along the Darling system in New South Wales, offer a range of aquatic resources, including fish, shellfish, hydrophytic plants, and water birds.

Before 25 ka, conditions were perhaps wetter, though cool to cold, but between 25 and 12 ka conditions were very much colder and drier, especially at the last glacial maximum. Much of this zone would have been inimical to human settlement at this time. Although people were on its fringes by 40 ka and occupying the 'dead heart' before 30 ka, many sites were abandoned at the height of the ice age.

People were at Mandu Mandu Creek rockshelter on the arid Western Australian coast *c.* 34 ka and left behind shell beads apparently used for personal adornment, as well as ocher carried there from the Pilbara area. As the sea dropped, offshore islands were incorporated into coastal territories as people followed the receding coastline. Today the bare rocks of the Montebello islands contain small rockshelter sites which reveal human presence at *c.* 27 ka, with both terrestrial and coastal resources represented in the deposits, and again between 7 and 10 ka, when the prograding sea was again near. These sites were not used between times and were abandoned when they again became offshore islands.

Thus models of changing land-use patterns put forward by arid region scholars all emphasize mobility and adaptation to changing environmental conditions and suggest small populations thinly spread across the arid zone. Diets may not have been greatly different from those recorded ethnographically in these regions. They are generally similar and broadly based and in addition to marsupials included reptiles, birds, larvae, tubers, fruits, seeds, and aquatic resources where available. Recent claims that grass and tree seeds might have been gathered and processed in the Pleistocene and particularly before the last glacial maximum are notable because although seeds are nutritious, their gathering and processing is laborious. For this reason, seed processing elsewhere in the world is seen as a key indicator of changes in human behavior connected to the appearance of new technologies, larger and more settled populations, and in places the establishment of agriculture. Its presence in an Australian form in preglacial arid Australia has significant theoretical relevance. Traces of seeds and other plant food remains from Pleistocene levels in Carpenters Gap in the northwest is complemented by pieces of grinding stones dating to *c.* 30 ka at Cuddie Springs some thousands of kilometers to the east. These carry usewear and residue traces suggesting the

processing of starchy and siliceous plants, evidence coincident with a local change to grasslands seen in the pollen record at this time.

Data from the Mungo region of western New South Wales indicate how favorable these lake systems were when lacustral conditions ensued. A range of resources – fish, shellfish, crustaceans, and birds – were taken. Fish may have been taken using nets and spears and possibly traps. A range of mainly small terrestrial game was also captured, and again in this region unspecialized grinding tools suggest at least generalized processing of plant foods and seeds during the Pleistocene.

Tasmania

Today, and for the last 12 ka, humans have occupied the north and east of Tasmania. In the southwest, temperate rainforest continues to exclude settlement. During the late Pleistocene, however, this situation was reversed (Hiscock, 2008; O'Connell and Allen, 2007). At times glacial deserts made the east inhospitable, while colder and drier conditions forced the rainforests in the southwest into refugia at lower altitudes, opening up the montane valleys to open forest with patches of grassland on limestone substrates in the valley bottoms. Since 1980 *c.* 30 sites, predominantly limestone caves have been located in the rainforest and *c.* 12 tested by excavation. The oldest, Warreen, was occupied *c.* 35 ka and all were abandoned by 12 ka, when warmer and wetter conditions encouraged the return of the forests, which drove out game animals and their human hunters. At the height of the last glacial maximum, the mountains had glaciers extending as low as perhaps 700 m above sea level, only a few hundred meters above some of the occupied caves. With temperature reductions of *c.* 7 °C and winds reducing temperatures sometimes tens of degrees, it was indeed an extreme climatic place, some 40° of latitude south of their ancestors' equatorial point of departure.

The cluster of known sites provides a rare glimpse at a regional pattern of Pleistocene behavior extremely different to that depicted for arid Australia. Here the subsistence strategy was the opposite of broad spectrum. There are no obvious vegetable staples which might have supported even small transient groups and the plentiful faunal remains repeat the same pattern from site to site. Up to 80% of bones from humanly consumed animals were from the single species *Macropus rufogriseus* – the Bennetts wallaby, supplemented in small amounts by wombat and platypus. In more than 630 000 animal bones processed from eight sites, there is not a single extinct megafaunal species represented, although some are present in nonarchaeological deposits in caves in the same region, suggesting that those species known from Tasmania had become locally extinct before human arrival, or that they were not hunted or scavenged.

Holocene Continuities and Changes

As the forests drove Tasmanians from the southwest, rising sea levels at the end of the Pleistocene cut off Tasmanian access to the Australian continent and for 8 ka the Tasmanians were deprived of human contact beyond their island. When reunited with the world at the end of the eighteenth century, they no longer made bone points, caught fish, or made fire, and were obliged to keep fire burning or rekindle flame from neighboring groups. Their technology comprised no composite or hafted tools, and consisted only of single-piece wooden spears, clubs, digging sticks, kangaroo skin capes, skin and kelp water containers, string, and small baskets. A simple stone-tool technology was compared by Europeans to Mousterian industries. While the loss of fish in the diet *c.* 4 ka may reflect some established island-wide taboo, this dietary loss was offset by the continued capture of seals and terrestrial mammals and an expanded range of shellfish species. In the recent Holocene, more use seems to have been made of the less-hospitable south and west coasts and people also used nearby offshore islands. Bundles of reeds tied in the shape of small canoes are known ethnographically where they were used as flotation devices.

In contrast, the end point of Holocene changes on the mainland differentiated Tasmanians and mainland Australians so distinctly that early explorers and anthropologists considered them different races. But while the Tasmanian devil and marsupial tiger or thylacine – both extant in Tasmania when Europeans arrived – had disappeared from the mainland when the dingo was introduced there from Southeast Asia or New Guinea *c.* 4 ka, few other Holocene changes can clearly be attributed to external influences. In particular, the temporal and distributional evidence for the appearances of small points, geometric microliths, and other tools during the mid- and late Holocene suggest different and regional origins within the country. While some of these tool types disappeared perhaps 1–2 ka in some regions, in the north larger bifacial points and other macroblade tools appeared more recently (Hiscock, 2006).

This proliferation of regional tool-types, increases in site numbers, site types, and the range of organic and inorganic artifacts to be found in them, together with the appearance of cemeteries, evidence for exchange networks, and labor-intensive specialized food procurement activities such as constructing artificial channels to capture migrating eels, has been taken as a package by some Australian archaeologists to promote a model of socioeconomic intensification in the late Holocene (David et al., 2006; Lourandos, 1997). Even though stationary sea level and the relatively young ages of these sites clearly promote better preservation and higher visibility, this package is contrasted with the Pleistocene and early Holocene, where population densities were supposedly lower, territories larger, people were less sedentary, there was less social ranking, and less complex food procurement strategies. Critics of this model question its testability in the archaeology, pointing to evidence that aspects of Pleistocene life may have been just as complex as that in later periods, and some prefer to continue seeking environmental explanations for the changes seen in the archaeological record (Hiscock, 2008).

The unsurpassed heritage of Australian rock art has been recorded, classified, and interpreted for more than a century. The ability to now date many of the varied styles directly is a recent revolution which is enabling the integration of art with other aspects of the archaeological record. Many new and ingenious techniques, such as luminescence dating of sand grains in mudwasp nests overlying painted surfaces, or dates that use carbon in oxalate salts to indicate the time when such

encrustations covered the art, are now demonstrating a long Pleistocene history for many paintings, providing a further window on the nature of hunter–gatherer intellectuality.

Australian Aboriginal Society and Culture: An Overview

Robert Tonkinson, The University of Western Australia, Crawley, WA, Australia

This article is a revision of the previous edition article by G. Cowlishaw, volume 2, pp. 956–960, © 2001, Elsevier Ltd.

Abstract

This article provides a brief overview of Aboriginal Australian society and culture, past and present. After 1788, those hunter-gatherers who survived introduced diseases resisted the British colonists along an uncontrolled, often violent frontier. Processes of alienation, displacement, institutionalization, discrimination, and racism debilitated them. The First Australians became a small, powerless, oppressed minority, overrun by an expanding settler frontier. There is, however, considerable cause for optimism.

Origins

The ancestors of the Aborigines came out of Asia and crossed the Australian continent during a period of lower sea levels about 50 000 years ago, then went on to eventually populate the entire continent. Mitochondrial DNA evidence shows that Aborigines are unrelated to all their neighbors, such as the Maori, Papuans, and Indonesians. Almost 200 years prior to colonization, Indonesians became the first outsiders to visit in search of highly valued *bêche-de-mer* (sea-cucumber) found along the northwest and north coasts. However, their mark on the land was negligible, in great contrast to that of those who followed. Estimates of the continent's population at the time of British settlement vary between 300 000 and one million (Mulvaney and White, 1987; Edwards, 1988).

Despite inevitable fluctuations in population densities, subsistence activities, and regional politics, there was a high degree of cultural continuity throughout the continent. Much of this sameness derives from their hunter-gatherer adaptation, which limits possibilities of diversification. Australia had few areas (such as the lower River Murray valley) capable of supporting high population densities. Mobility and large ranges of movement typify their adaptation to much of the continent's interior, where travel in small dispersed groups was the norm. Multiple bonds linked individuals to homeland sites and territories; that more than 200 languages were spoken supports the fact of strong anchorage to homeland territories.

Social Organization

An estimated 500 or so 'tribes' existed at the time of the British invasion (see Berndt and Berndt, 1988; Burridge, 1973 for comprehensive accounts of traditional Aboriginal society and culture). The visible, face-to-face local group was the band, averaging between 15 and 25 people, which varied in size, and comprised a core of closely related people. Gender and age were the two most important status differentiating criteria. However, mature males predominated, especially in politics and religion, and they claimed primary responsibility for ensuring the society's cultural reproduction. Strong bonds of kinship, friendship, marriage, dialect, exchange relationships, and shared religious responsibilities also turned people's attention outward to regional cultural connections. The 'range' or normal circuit of a band typically overlapped to a certain extent with those of neighboring groups. This larger society could never be a permanent fixture, but was temporarily realized in the form of periodic gatherings two or three times every year, at a location possessing sufficient water and food resources to support a large group (Tonkinson, 1991). An integral element of Aboriginal society, these 'big meetings' are still very important in the lives of many remote-dwelling Aboriginal people. They include an early and obligatory settlement of all outstanding disputes, initiation of males, performance of rituals, exchange of sacred and mundane knowledge and information, items of material culture and other lore, arrangement of betrothals, and planning for future meetings. They are exciting occasions, filled with ritual performances, gossip, and romance.

Australia's Other Indigenous Minority: The Torres Strait Islanders

Many Australians are unaware that Australia has two Indigenous minorities. Traditionally, most of the 60 000 or so culturally Melanesian people of the Torres Strait Islands and northeastern coast of Queensland were tropical horticulturalists, living in settled villages and subsisting from their gardens, fishing activities, and some foraging for wild foods. Today, most Torres Strait Islanders live on the mainland and many have successfully integrated in the wider society. Socioeconomically, they have generally fared better than the Aborigines in their fortunes since the European invasion. Space precludes further discussion, but the interested reader should refer to Beckett (1990); and AIATSIS (2012).

European Impacts and Aftermath

European colonization of Australia began near Sydney in 1788, when the British established a convict settlement and used the legal fiction of *terra nullius*, 'empty land,' to claim the entire continent. Once settlers arrived in large numbers, an unregulated frontier was soon being pushed westward, provoking

Aboriginal resistance (Reynolds, 2006). The settlers, understanding nothing of the Aboriginal people's complex social organization and religion, increasingly depicted them as 'treacherous savages' who failed to make productive use of the land. Resistance was inevitable, leading to protracted hostilities, including massacres, mostly of Aborigines; eventually, superior technology prevailed. Introduced diseases also killed countless Aboriginal people, prompting characterizations of them as a 'weaker race' and the enactment of ameliorative legislation, which was sometimes labeled 'soothing the dying pillow' (Broome, 2010). In many parts of the continent, colonial authorities sought to contain the survivors (many of whom had been reduced to destitution after it became impossible to maintain traditional subsistence activities). They were institutionalized, given blankets and subject to many restrictions aimed at isolating them from settler society (Rowley, 1970; Rowse, 1998). Some remained on pastoral and cattle properties, where they labored. Others were sheltered by Christian missions, which had scant initial success with the people who, unsurprisingly, for the most part, evinced little interest in this new religion – though Christianity was later embraced, to varying degrees, in many places.

Following federation of the six Australian states in 1901, state authorities passed increasingly restrictive legislation that made Aborigines captives in their own land. Meantime, the Australian frontier had moved west and north into the arid interior. For a long time, 'the outback' or 'bush' was highly masculine, being considered no place for a white woman. Inevitably, then, frontiersmen would take Aboriginal women as sexual partners (sometimes disguising them as males). A major consequence was the rise of a mixed-race population, which eventually came to greatly outnumber Aboriginal people of full descent.

The period of unprecedented national prosperity that followed World War II was not shared by many Aboriginal people. This situation of poverty amid plenty aroused concern in some quarters of the wider populace, and various organizations devoted to Aboriginal welfare sprang up. So did Aboriginal protest and resistance movements. Led mainly by urban activists, these groups decried racism and neglect, and agitated for reforms and urged pan-Aboriginal unity. In 1967, a national referendum was held, the outcome of which was an overwhelming 91% vote to include Aborigines in the Census; it also empowered the Federal Government to make laws pertaining to Indigenous Australians.

On Australia Day, 1972, Indigenous activists set up a 'Tent Embassy' (representing a displaced nation), opposite the federal parliament in Canberra, demanding land rights, compensation, and protection of heritage. The 'Embassy' remains to this day as a constant reminder of unfinished business and a focal point for Indigenous protests. A change of Federal government in the early 1970s brought new policies aimed at increasing the level of Aboriginal self-management; it promoted Indigenous community councils and land councils and created service organizations. There were many setbacks and well-publicized scandals about alleged financial malfeasance, but the following decades saw the rise of powerful Aboriginal-controlled regional land councils and ancillary service organizations.

By 2000, the conservative Coalition federal government in power was taking a tougher line on Indigenous affairs. It later disbanded the Aboriginal and Torres Strait Islander Council, the national Indigenous elected representative body, raising fears of a new paternalism. In 2007, it intervened in the Northern Territory, using Defense personnel, ostensibly to protect Aboriginal children against sexual abuse. The Northern Territory Emergency Response (usually labeled 'the Intervention') imposed strict controls on Aboriginal people living in remote reserves; these included management of welfare benefits, especially where children are deemed to be neglected; restriction of access to alcohol and compulsory acquisition of some land areas. The Intervention continues to divide opinion. When the federal Labor Party won government in the 2008 election, it retained, modified, and extended the Intervention. Labor's stated major policy goal in Indigenous affairs is to close the immense socio-economic gap that persists between Indigenous Australians and the rest of the population. In life expectancy, for example, it is 12 years less for Indigenous men and 10 years for women.

In remote regions of central and northern Australia today, Aboriginal people retain a significant tradition orientation despite strong Westernizing influence on lifestyle and diet. They continue to enjoy hunting and gathering, more as leisure activities than subsistence necessity, but with vehicles, guns, and iron tools. Continuities with the past have remained important in the values and behaviors surrounding kinship and social relations, and in recent decades there has been a strong emphasis on cultural revival. There is much evidence of renewed and determined opposition by Aboriginal people to cultural absorption, consequent on material and cultural impoverishment, a legacy of the colonial past.

Economics and Kinship

Broadly speaking, the subsistence economy was classically hunter-gatherer: men hunted larger animals, such as kangaroos, crocodiles, and emus, while women and children gathered vegetable foods and hunted small animals (Keen, 2004). The nature of the seasonal round depended very much on climate, particularly rainfall, since most of the continent is arid. Everywhere, though, people possessed an encyclopedic knowledge of their environment and, for example, practiced strategic burning to facilitate the yields of both floral and faunal food sources. Like other hunter-gatherer societies, those of the Aborigines were small in scale, 'familistic,' kinship-based, and broadly egalitarian. A key integrating institution was the system of classificatory kinship, in which every kin-term encodes expected behaviors and responsibilities. Wider groupings also featured, and Aboriginal societies are unique in the complexity of their social category systems (moieties, sections, and subsections) that complement and overlie kinship systems. Activated for certain purposes, most often during rituals and major rites of passage, these social categories are divorced from economic activities. The absence of formal institutions of social control meant heavy reliance on individual self-regulation. Aboriginal people use kin terms in addressing and referring to others, indicating that, ideally, the relationship entails mutual obligation and responsibility. In rural and remote Australia, webs of kinship tend to be larger and more complex than in urban areas. Historical factors such as dislocation from country, institutionalization, and removal from parents, separated and dispersed many families.

Religion and Worldview

The Aboriginal cosmic order comprises human society, the plant and animal world, the physical environment, and the spiritual realm. Across most of the continent, worldviews were grounded in two closely interrelated concepts: 'the Dreaming' (also called the Dreamtime) and 'the Law' (Berndt, 1974; Stanner, 1979, 1989). Broadly, the Dreaming explains how things came to be as they are, and embraces past, present, and future. The Law specifies how life is to be lived according to jural rules instituted by ancestral beings in the creative epoch of 'the Dreaming.' It specifies what from the founding era was to be emulated and what was tabooed, and remains part of lived reality for most remote-dwelling Aborigines (Maddock, 1982; Keen, 1996).

Accounts of the Dreaming are at base broadly similar across the continent. Here is a brief example from the Western Desert: long ago, large and beautifully decorated humanoid-animal beings arrived in a featureless, empty land. Possessing super-human magical powers, they hunted, gathered, and exchanged religious objects, rituals, and knowledge. The extensive tracks of the major beings crisscross the land and are commemorated in mythology, song, and ritual. They left behind human societies and a blueprint for living. There were also localized creative beings, whose exploits are commemorated among smaller groups. Prominent or distinctive shapes and features in the landscape inspired much mythology; for example, a claypan created when a weary creator lay down to sleep, or a canyon forged by the passage of a huge rainbow serpent (Meggitt, 1962; Munn, 1973).

The ancestral beings eventually 'died,' worn out by their creative work, and turned into landscape features before, as spirits, they eventually returned to the spiritual realm. The 'life essence' they had exuded to animate the flora and fauna remained as the source of all life. These departed creators are believed to retain a strong interest in human affairs, and their spirit-being associates play a vital role as intermediaries between human and spiritual realms. Though unreachable in the course of everyday mundane activities, they or their spirit-being messengers are amenable to contact during altered states of consciousness, notably dreams, reverie, and rituals.

People's strong sense of security was grounded in their encyclopedic environmental knowledge. Their responsibility was to nurture country and resources, obey the Law, and perform the rituals necessary to maintain the fertility of flora and fauna. Multiple totemic associations link individuals to the Dreaming powers, and manifest a powerful urge to maintain intimate relationships between humans and nature. In the Western Desert region, for example, conception totemism provides every person with a unique account of her/his transition from spirit-child to human, linking everyone to place, spirits, and other humans and, most significantly, into the realm of the Dreaming itself.

Maintaining Ethnic Identity and Pride

About 400 000 Australians (*c.* 2.3% of the total population) today identify themselves as Aboriginal, and many more people with Aboriginal ancestry have melded into the population at large. About 80% of Aborigines are urban dwellers, often somewhat distanced from 'traditional' roots but proud of the cultural achievements of their ancestors. In remote regions, the Dreaming and the Law remain part of most Aboriginal people's lived reality and, together with kin and country, are essential components of their ethnic distinctiveness. Like the population at large, about 80% of Aboriginal people live in urban areas. Just over half of them live in just two states, New South Wales and Queensland, but are small minorities in both, whereas in the Northern Territory they constitute a significant (if still minority) proportion of the population. Rates of intermarriage between Aboriginal and non-Aboriginal people are increasing. Aboriginal identity is officially recognized via two criteria: self-identification and the recognition of this claim by an unspecified 'Aboriginal community.'

The spectrum of Aboriginal people's social situation in Australia today is vast, covering a small minority of well-educated bureaucrats and professionals occupying senior positions, and at the other extreme those at the bottom of Australia's socioeconomic pyramid, including a minority living in remote regions and speaking English as a second language. Although the Aboriginal population is disadvantaged according to virtually all social indicators, it is united by pride in their identity and the ongoing struggle for full equality (Sutton, 2009; ABS, 2011). Under current Australian law, all citizens ideally share the same rights and obligations, but Aboriginal people are demonstrably also subject to inequality and racism, both structural and personal.

In regions where alienation from land and traditional resources has been longest and strongest, Aborigines are of mixed descent and hugely outnumbered. Their sense of unity derives less from any common territorial roots than in a shared history of marginalization, alienation from land, oppression, and racism. For them, identity can be a major concern, since they may face 'hints of inauthenticity', especially from sceptics among the non-Indigenous majority. Some objectify their Aboriginality and associated traditions and have been active in cultural borrowing from other areas. The slogan 'cultural revival is survival' is linked to issues of identity, pride, land rights, local solidarity, and belonging. Many Indigenous people, across the continent, are increasingly aware, partly as a result of the land rights movement and recognition of native title, of the potential held by tradition to legitimate their claims to a share of the country's resources. Legislation, particularly regarding Aboriginal heritage protection and native title, is one of the few tools available to them for the effective exercise of some measure of power against the hegemony of the 'whitefella.'

Language

Although English is the first language of most Aboriginal people, statistics from 2008 report that one fifth of Indigenous people aged 15 years and over and 13% of Indigenous children (aged 3–14 years) speak an Aboriginal or Torres Strait Islander language. In parts of northern Australia, particularly, creoles are spoken. Many language centers operate in rural and remote areas, and there has been considerable investment in language

research and recording, and in supporting language education. There are some bilingual schools, particularly in central Australia and the Northern Territory, but in recent years bilingual education has become controversial, with opponents claiming that it retards the effective acquisition of English and mainstream education. About 70% of Indigenous children (aged 3–14 years) and 63% of Indigenous people aged 15 years or over are involved in cultural events, ceremonies, or organizations. Some two thirds of Indigenous Australians identify with a clan, tribal, or language group. In Southern Australia, many languages have been revived, and many people believe they are crucial to cultural health, a keystone of identity, Law, and land claims.

Art Production and Sport

Petroglyphs (rock engravings) and rock paintings have been a part of Aboriginal culture for at least 40 000 years, and everywhere ochres, and other sources of color, were used. In connection with rituals, body decoration with these pigments was common; also, in the north, decoration of burial poles and in the desert interior, ground drawings and sand paintings, were common. Pigments held symbolic significance, for example, red ochre was highly valued as the metamorphosed blood of the ancestral creative beings. The adoption of synthetic paints and other portable enduring materials has resulted in new media and forms of visual art expression being widely adopted. Basketry, pottery, sculpture, and glasswork are all part of the prodigious Aboriginal art production, and the art market now provides a significant source of income for many Indigenous artists. Outputs on canvas and bark have risen dramatically and state and national awards and major exhibitions encourage prominent artists, whose works also sell well in overseas markets.

The most widely recognized Aboriginal people in Australia's media today are sports stars, who are significantly overrepresented in two of the most popular codes: Australian Rules football (10%) and rugby (11%). Many women have achieved sporting fame, notably tennis star Evonne Goolagong and Olympics gold medal winner Cathy Freeman. Many Aboriginal people take part in a variety of amateur sports such as netball and basketball.

Sovereignty Issues and Relations with National and Local Governments

Organized Aboriginal political activity and calls for reform and equality date back at least to the 1930s, but intensified in the 1970s when articulate leaders drew inspiration for strategizing from Black Power movements in the United States. Resistance accelerated in the 1970s with the institution of an elected advisory body, the National Aboriginal Consultative Committee. The NACC's most prominent leaders and spokespersons were Aboriginal people of mixed descent, whose ethnic identity often came under fire, both from White Australian opponents and some Aboriginal people in remote areas.

Other challenges for Aboriginal nation-builders have been to overcome the problems of distance and diversity of lifestyle and outlook and to present a unified front and positive self-image in the face of media coverage that is often negatively focused on crime and 'dysfunction.' Any claim to represent Aboriginal people is potentially conflict with strongly maintained traditional values surrounding local autonomy, which limit the ability of individuals to 'speak for' others. Following colonization, and especially after Federation, Aboriginal people were not included as citizens with the full array of rights entailed in this status, and relations with governments at all levels have been fraught. Over many decades prior to the 1980s, a largely hidden policy of removing children by government fiat from their natural parents was in force, and for many its consequences were dire. In the 1990s, there was a well-publicized national inquiry into 'the stolen generations.' A 1994 Australian Bureau of Statistics survey revealed that more than 10% of indigenous Australians over the age of 25 reported having been separated and raised in isolation from their natural families. Many non-Aboriginal Australians were deeply moved to learn how severe, widespread, and recent were these traumas and gross violations of human rights. Several organizations are currently working toward the goal of reconciliation between the majority population and the indigenous minorities. In 2008, Labor Prime Minister Kevin Rudd offered a formal apology to members of the stolen generations, the symbolic importance of which was massive. Broadcast nationwide, it triggered emotional reactions across the Australian population.

Land Rights

For the last 50 years, land rights have loomed large in Indigenous political struggle. Notable breakthroughs include both federal and state legislation specifically recognizing Indigenous Australians' claims of ownership (e.g., the Aboriginal Land Rights (Northern Territory) 1976). The most momentous legislation to date is the Native Title Act 1993. In 1992, in *Eddie Mabo and others v the State of Queensland*, Australia's High Court accepted that, under common law, the native title of Australia's indigenous inhabitants could be recognized, invalidating *terra nullius*. However, the Court also found that grants of all freehold and some leasehold titles by the Crown extinguish native title. This left most of southern and eastern Australia unavailable for claim; and only 10–30% of Aboriginal people stand potentially to gain some security of tenure. The early promise of Mabo has been dulled by successful Federal Government moves to weaken the Native Title Act and by protracted legal challenges to the claimants, but there has recently been some progress in speeding the claims process.

Outlook for the Future

Today, generalizing about Aboriginal Australia is difficult because of its enormous regional and social diversity. Certainly, there will be an increasing melding of the two 'nations' in Australia, though the contrasting population pyramids (showing a much younger, but shorter lived, Indigenous population that is increasing more rapidly than the national rate) will not soon blend into one. While there is much discourse, by

politicians, media commentators, and many within and outside the Aboriginal population, there is no consensus as to the causes of enduring inequality or the methods by which it can be ameliorated. Many non-Aboriginal Australians continue to blame 'dysfunction,' welfare state provisions and so on, and discount the debilitating impacts of a long history of dislocation, marginalization, oppression, and racism.

Of considerable concern to Indigenous leadership and organizations, governments and NGOs have been the glaring disadvantage of Aborigines and Torres Strait Islanders on every measure of well-being, especially health, education, and employment (2010). For example, median incomes for Aboriginal people are 35% of those of non-Indigenous Australians. Raising educational attainment and reducing welfare dependency are also often-stated goals, and there is a continuous debate about how best to achieve those goals. Health problems remain severe, and Western lifestyle diseases, notably diabetes, cardiovascular diseases, and renal failure now claim a disproportionately high number of victims. Alcohol abuse and associated violence and death are widespread. Indigenous people are also twice as likely as non-Indigenous people to be daily smokers and to suffer higher levels of psychological distress and shorter life spans than the population at large. In many areas, Aboriginal community life is also severely marred by massive and chronic unemployment and domestic and other forms of violence. The failure of 40 years of policies promising self-management has led many prominent Aboriginal leaders to push for a complete rethinking of government policies. Some urge the empowerment of communities to tackle head-on the social ills plaguing them and to devise their own strategies to escape from 'welfare dependency' and engage productively with the mainstream economy.

Influential Indigenous people are now working in the professions, academia, media, politics, and business. There is a Indigenous-controlled television network. University graduation rates are increasing, and leadership programs have successfully launched hundreds of young Aborigines into well-paid careers. Educational attainment for Aboriginal and Torres Strait Islander Australians has increased appreciably since the mid-1990s. In 2008, 37% of Aboriginal and Torres Strait Islander people aged 18 years and over (adults) had attained a minimum of Year 12 or a skilled vocational qualification, more than double the rate in 1994 (16%). Over the same time period, those completing a minimum of Year 10 or basic vocational qualifications increased from 48 to 71%. While relatively few Aboriginal and Torres Strait Islander adults continued on to complete a Bachelor degree or above, the rate increased to 5% in 2008.

Aboriginal people have, until relatively recently, been excluded from control over any significant resources. However, big changes have been occurring and more are imminent, particularly in Western Australia and Queensland, the mining states currently accounting for much of Australia's strong economic situation. After decades during which local Indigenous people were almost entirely excluded, the industry now provides training programs and employment in mining and associated service industries. Also, with the recognition of land rights and native title, mining royalties and other income from the industry are now flowing to affected Indigenous communities and land councils in many remote regions. Major organizational challenges nonetheless remain: principally, the creation and regulation of systems that ensure an equitable redistribution among Aboriginal land owners, with mechanisms to guarantee long-term benefits to affected populations.

Indigenous Australians are now an increasingly visible physical and cultural presence in most major cities and a significant demographic component of local populations in the sparsely populated northern and central regions. The situation is complex, but the cessation of restrictive discriminatory laws and the success of Aboriginal people in a range of activities have all contributed to notable improvements. (A large surge in people identifying as Aboriginal occurred in the 1990s and could be related to this more amenable social milieu.) Notable Aboriginal achievements in art, music, literature, sport, film, and dance have received much media attention; there are nationally televised award nights, and positive images of indigenous people appear to be seeping into the national consciousness. The rhetoric of survival and resistance has become more muted, displaced by a more culture-centred emphasis on Aboriginal commonalities and shared aspirations to mainstream participation. The gap separating them from the mainstream is still considerable, but is narrowing and there are grounds for optimism.

Abstract

When global surveys detail the countries to which people would most like to migrate, Australia consistently emerges at the top of the league table, or very near to it. The grounds on which these global judgments are arrived at are never made clear. But it is assuredly the case that Australia's international image is that of a prosperous, stable, and successfully multicultural nation. It is seen as forward- rather than backward-looking, notably free from the historical enmities and enduring conflicts which afflict other, late capitalist societies. Broadly speaking, this assessment is accurate enough, but Australia is an increasingly complex society in which less progressive cultural features are discretely hidden from view.

Prosperity and Paradox

Australia is assuredly a prosperous society, ranking about sixth in the world today, which means that its affluent middle classes are structurally and culturally all-important. Australians enjoy one of the highest rates of private property ownership in the Western world: household possession of a second or third vehicle, including expensive 4WDs, is commonplace; an extensive range of costly consumer goods is the norm; and even the ownership of a second dwelling for vacation use is considered nothing untoward. There is a strong commitment also to costly hedonistic activities, including multiple forms of gambling which have become a significant source of revenue for the country's two largest states. According to reliable sources, Australian adults lose on average AUD$1300 per year on gambling, the highest rate in the world. The country comes to a complete halt when the Melbourne Cup, its premier annual horse racing event, takes place; the turnover in bets on this race alone totaled AUD$93.6 million in 2011.

Australia is also a society distinguished by political stability, particularly by comparison with other nation states which grew rapidly in the twentieth century through migration. Unlike South Africa or Israel, for example, the political process has throughout been strikingly free from outright conflict. Constitutional crises have been rare, elections are routine affairs, and changes in government at federal and state levels are uncomplicated. This is by no means to suggest that the political arena is free from significant lines of cleavage, or that public confrontations are unknown. The divide between Aboriginal and non-Aboriginal interests is substantial, and public expression of it is recurrent in a diversity of ways. As we shall see, racism and xenophobia sometimes seem only just below the surface of everyday life, and how the country should deal with the arrival of refugees by boat from the north is a source of recurrent dispute. But the absorption of major social conflicts is undoubtedly among the more pronounced qualities of the political system in its broadest sense (see Megalogenis, 2012).

Yet despite this broadly based affluence and noteworthy political order, it is also the case that a distinct sense of unease and uncertainty over Australia's national and cultural identity is often remarked upon, particularly by authors, playwrights, and poets. As the end of the twentieth century drew near, David Malouf, who is one of the best-known authors and respected commentators in the country, suggested that Australians attended excessively to the opinions of others, including Americans and Asians, and should pay more attention instead to "our own better and freer and more adventurous selves" (Malouf, 1998). Now that we are well into the twenty-first century, it is clear that this is easier said than done, especially as a result of momentous changes of late in the political economy of East Asia, for this cultural unease and societal uncertainty continue apace. At one level, this relates to how Australians are different from one another, more specifically what is entailed by multiculturalism, and how it is defined and ordered in particular ways, for there are, in the view of some, cracks in the façade which are not easily papered over. At another level, it concerns the position of Australia in the modern global system, above all in light of the growth in material prosperity being increasingly driven by complex and uneven trading relationships with China.

Rural Change

Australia's small and peripheral economy – the current population is just over 22 million and ranks 50th in the world today – has long been integrated into the global marketplace, mostly to distinct economic advantage. Throughout the first half of the twentieth century, the export of agricultural produce and minerals to Britain and mainland Europe generated a prosperity from which only particular minorities were wholly excluded.

This affluence was sustained after World War II as new international markets were added to traditional ones. By the early 1970s, however, this export-dependent economy proved distinctly vulnerable to changed global conditions (Bell, 1997), and in rural areas the major impact fell on the small to middle-size farms. Declining commodity prices, increased interest rates, price hikes in key inputs (such as fertilizer), and rising transport costs impacted most severely on the bottom 25% of the rural hierarchy; and their problems were compounded by the loss of wage-earning opportunities as well as cutbacks to infrastructure and welfare services. By the end of the twentieth century, the combined impact of these changes had resulted in the loss of large numbers of young people to the cities, the closure of somewhere between 2000 and 3000 production

units each year, and increased dependence on welfare payments among the already marginal, along with a widening of the material divide between the prosperous and those who struggled to survive, the 'battlers in the bush.'

Lawrence (1987) made it clear that these changes to the rural class structure were inseparable from the increased hegemony of a small number of transnational corporations over the agricultural system. These corporations exercised tight control over the supply of critical inputs to the rural sector (mechanical equipment, building materials, seeds, and so on) as well as its major outputs (processing, canning, and transportation). The larger units of rural production that were owned by, or were contractually integrated with, these transnational organizations realized higher rates of profit than previously, but smaller farms found it increasingly difficult to survive and were often swallowed up by larger ones.

These processes have been compounded into the current century to the point at which just two transnational corporations exercise effective dominance over the country's domestic food sector while using their profits to expand into new spheres of commerce and service industry. But the rural sector has also been greatly impacted by a severe decade-long drought which has, somewhat inevitably, taken its greatest toll on moderate to small-size agricultural units. To be sure, there is nothing new about drought conditions in Australia, the driest continent on the planet. But the impact of the most recent one not only highlighted, but was also compounded by, environmental problems generated by long-term economic exploitation and political mismanagement. The most significant region in this regard has been the vast Murray-Darling river system which covers major areas of Queensland, New South Wales, and Victoria, before entering the Southern Ocean in South Australia. Although pivotal to the entire country's material well-being as a major source of foodstuffs for domestic and overseas markets, decades of agricultural pollution, uneven water usage, and widespread wastage of water due to a lack of infrastructural maintenance have been detailed in a series of scientific reports generated over at least two decades. But rivalries between the states with different commercial realities to protect, and the Federal Government's inability to moderate or override these political divisions, have resulted in delay and deadlock.

Community protest has become a recurrent feature across this rural landscape, and not only inside the Murray-Darling river system. As mining corporations have penetrated rich agricultural areas in the eastern states to explore the prospect of shale gas production, families and communities have raised what are by now customary concerns elsewhere about the impact of intensive 'fracking' on valuable farmland and irreplaceable water supplies. What is common to these developments is that ordinary folk, with no track record of political protest, openly vent their substantial concerns about community survival and an equally profound disenchantment with government incompetence and political deception. It is frequently the case that, in the course of grassroots mobilization, these external intrusions bring to the fore and even exacerbate local differences and regional distinctions; but the root sense of belonging to specific locales, and the authentic ways of rural life inscribed over these landscapes, is by no means compromised as a result.

A further environmental development which has impacted greatly on rural communities in recent times has been the explosive spread of feral creatures, including such non-native animals as wild dogs, camels, buffalo, pigs, and most notorious of all, the cane toad. Not only do some of these creatures pose a threat to the survival of small, indigenous species, which might otherwise be a significant attraction in rural tourism, along with the kangaroo population which is widely held to be in 'plague' proportions, their combined impact has the capacity to drive even moderate-size farms to the wall.

In these complex circumstances, the independence and the fortitude of farm family producers, so integral in the past to the material prosperity of Australia, become increasingly illusory. The cultural significance of these changes is as wide-ranging as their economic ones. The bush has always provided the more powerful symbols from which cultural specialists forged narratives about the distinctiveness of the Australian character and its relation to the environment. Self-reliance, egalitarianism, and mateship are all morally weighted idealizations drawn from outback experience, and all have been integral to the process of distinguishing Australian culture and the nation from their European origins. When the realities of rural experience are characterized by increasing inequalities of class, threats to community life, corporate domination and environmental dispute, the bush and its authentic way of life inevitably lose their iconic value in the political construction of Australia as a distinct cultural space.

Migration, Urbanization, and Multiculturalism

The majority of Australians reside in a handful of capital cities and their suburban satellites at different points of a vast coastline. These are the metropolitan centers which expanded exponentially with the arrival of immigrants post World War II and therefore became the crucibles of Australia's experience with multiculturalism. Hugo, a demographer, has noted that Australia underwent an unparalleled transformation throughout the twentieth century from "an overwhelmingly Anglo-Celtic, homogenous population in which 95.2% had been born in Australia, the United Kingdom or Ireland, to one of the world's most multicultural societies" (Hugo, 2002), Richards, a historian, has argued that the relative absence of major disharmony and dispute throughout this social transformation stood as testament to the success of Australia's commitment to multiculturalism(Richards, 2008).

The main warrant for these positive accounts has been the way in which the country absorbed the huge postwar intake of immigrants, and the experience of the second and third generations (see contributions to Jupp, 1988). Between 1947 when the population stood at 7.5 million and 1987, some four million immigrants entered the country. Since the United Kingdom and Ireland were no longer able to meet Australia's demand for labor, by the 1960s substantial numbers were recruited from southern Europe and the Levantine. Regardless of their places of origin, these new immigrants were offered citizenship to encourage permanent residence.

The result was an exceptional increase in Australia's culturally hybrid character. Inner city suburbs were rapidly transformed from predominantly Anglo-Celtic working class neighborhoods

into multiethnic lower-class suburbs. Alternatively, these new Australians gravitated toward the burgeoning outer suburbs of cities like Sydney and Melbourne where opportunities for wage employment in modern factories and relatively cheap housing were to be found. The crucial development was that overall (and there were some exceptions) immigrants from countries like Italy, Greece, and Yugoslavia, tended to loosely cluster in a range of residential areas rather than becoming concentrated in inner city ghettoes. This pattern of clustering, the building blocks of which were informal familial and friendship networks, allowed new arrivals to gain a foothold residence- and occupation-wise with the assistance of fellow ethnics who had arrived before them. Subsequently, it was relatively straightforward for themselves and their children to move upward socially on the occupational ladder and outward spatially to better serviced, more prestigious suburbs. Most important of all, upcoming generations married extensively across ethnic boundaries and expanded their friendship circles similarly.

All this was made possible in the second half of the twentieth century by a steady growth in societal prosperity in which second and third generations were able to share. In addition to acquiring the material trappings of the Australian middle class, they were able to retain select aspects of ethnic identification which, for the most part, were discretely rather than aggressively expressed, as was considered appropriate to 'the Australian way of life.' Speaking in one's native language around the home was coupled with the ordering of domestic space, the choice of foodstuffs, the organization of entertainment, especially participation in sport, in ways considered consistent with being Italian-Australian, Greek-Australian, and so on. On a more public plane, food and dance carnivals as well as ethnic clubs signaled and sometimes satisfied a sense of nostalgia for a cultural inheritance left behind several decades previously. Particularly among immigrants of West European origin, visits to the village or town of birth took on the character of a secular pilgrimage, but the upshot was generally to underscore the all-round benefits of long-term residence in Australia and the formal acquisition of citizenship.

These generalized processes could be readily glossed by the country's political elite as solid, even incontrovertible, evidence of the assimilative properties of a tolerant, open-handed, and relaxed late-twentieth-century Australia. Government agencies highlighted the achievements of multiculturalism, which had been adopted as state policy in the early 1970s. In the past decade or so, however, this progressive narrative has come under close scrutiny for several reasons.

The first is that a more complex picture has emerged from the social analysis of a greater diversity of ethnic immigrants, the organization of their everyday lives, and their connectedness with their places of origin. Thomas (1999) described in detail how migrants from Hanoi construct their suburban homes and gardens in intricate fashion to sustain their cultural traditions; but behind these practices is to be found a deep-rooted sense of fear and resentment, hardly surprising considering the mammoth displacements to which they have been subject. Baldassar (2001) argued that Italian-Australians return to their home villages with all the trappings of material success, but those who have stayed behind are often unimpressed, so that the returnees get bound up in a "circular quest for an increasingly elusive identity." Hyndman-Rizik (2008) argued that Maronite-Christians, who have been migrating to Australia since the 1950s and often been economically successful, can rise socially only so far before hitting a glass ceiling. They return home with high expectations of being respected there, but the result instead is a sense of being out of place in both Lebanon and Australia. These, and other studies, suggest that, behind the immediate benefits of material prosperity, there are many issues concerning the choice and expression of social identity which are hidden from view.

The second reason is that there has been a growing sense of resentment and hostility among some immigrant populations, especially the second generation of adults now assessing the life chances of their own offspring, that in order to become fully recognized as Australian, it has been obligatory to meet the expectations and beliefs of the Anglo-Celtic core which retains, or at least believes it retains, control over the key standards or mores which define membership of Australian society. This reaction from below has become pronounced in recent times because this hegemonic positioning was repeatedly articulated by Prime Minister John Howard who led a highly conservative Federal government between 1996 and 2007. Hage (1998, 2003), a sociologist, has addressed this issue analytically. While not specifically targeting multiculturalism as such, he argues that powerful agents in and around the modern state articulate a nationalist discourse which lays out, if not determines, the terms on which cultural others might be included within mainstream citizenry. This nationalist discourse, Hage states, is "not necessarily about excluding/destroying otherness but about regulating the modality of inclusion" (Hage, 1998: 174), and it is the fantasy of a 'White Nation' shared by groups which would not readily consider themselves ideologically allied. Hage's analysis does not engage much with the commonplace discourses of ethnic populations, nor the tensions and conflicts which disrupt their everyday worlds, but supporting evidence can be gleaned from other sources.

This brings us to the third, closely related factor, which is the proposition that there is a façade-like quality to multiculturalism: below a veneer of tolerance is to be found a sediment of xenophobia which from time to time explodes into the public domain. The impact is considerable because these occasions are so thoroughly turned over by the media. The most dramatic episode of this type comprised 'the Cronulla riots' of 2005 (see Cowlishaw, 2007) named after the beachfront suburb of Sydney in which they occurred, and involved several thousand predominantly young men aiming to target 'Lebanese' people. The trigger was an attack on two lifesavers by men of Middle Eastern appearance, while the rapid mobilization of this assembly was facilitated by text messaging and media coverage. The crucial point to recognize is that the label 'Lebanese' serves as a shorthand in some popular discourse for the Arab Other, an imagined population of outsiders who, it was assumed by the rioters, do not, and never will, integrate into the 'White Nation' of which those involved considered themselves members. The beachfront at Cronulla, itself an icon of Australian paradise and its relaxed culture, had to be reclaimed from 'uncivilized Arabs' with no right to be there. Sociological and pseudosociological accounts of the riots proliferated in the aftermath, but the idea that an ugly thread of racism is barely hidden by a veneer of multicultural harmony was commonly encountered.

By far the most important development has been the long-running crisis focused on the arrival on Australia's northern shores of asylum seekers from the Third World, notably Afghanistan, Iraq, and Sri Lanka. The number of refugees involved are insignificant by contrast with the scale of the problem facing prosperous European countries; Australia currently ranks 68th in the world on a refugee-per-capita basis. But, as has frequently been pointed out, the threat of 'invasion from the north' has long been an element of conservative nationalist discourse, so that the arrival of unheralded boats in unspecified number from Indonesia is rapidly incorporated into overblown scenarios about serious breaches to national sovereignty. The incident which received most international attention involved the *Tampa*, a Norwegian freighter which in 2001 responded to a request by Australian authorities to rescue over 400 refugees from a sinking vessel, only to find that the government had no intention of allowing them to enter Australian waters. There is no doubt that the Howard government's 'hard line on illegals' found extensive support among the Australian public, including its 'Pacific solution' involving the incarceration of refugees in processing centers overseas. The handling of asylum seekers has proved intractable and it continues to generate tensions with Australia's closest neighbors: but it has also exposed latent xenophobic sentiments at the top and the base of the social hierarchy.

The Middle Classes and the Changing Political Economy

The distinctiveness of social class in the Australian context has been regularly addressed in the sociological literature, including the widespread notion that, relatively speaking, this is a classless society. This belief is, or perhaps more accurately was, less about the presence of classes as the prevalence of egalitarianism – the idea of everyone being equal, notwithstanding significant lines of social differentiation – so that patterns of deferential behavior considered pervasive in especially British society were absent by comparison. In historical terms, the absence of an aristocracy or landed gentry was considered critically important (see Connell and Irving, 1992).

Presently, sociological analyses are particularly concerned to unravel the social intricacies of Australia's heterogeneous middle classes, which contrast markedly with those whose influence has been on the wane for some time. These interpretations are informed by the work of Bourdieu, and focus in particular on the cultural distinctions between a relatively young, prosperous, and fully urbanized middle-class stratum, and an older, less well-off, and predominantly regional one. Bennett et al. (2001) argue that the major source of their contrasting cultural tastes lies in the realm of formal education, so that those with tertiary-level qualifications are able to position themselves in Australian society in distinctive ways. It is, for instance, critically important to their self-identification that they take great care of the body, a significant site of pleasure and satisfaction. Survey materials reveal that professionals and managers participate extensively in sporting activities (tennis and golf) rather than being mere spectators. By contrast, supervisors and manual workers are inclined toward passive engagement, so that as a general rule the less well-off you are, the less inclined you are to be physically active.

Then again, significant differences are to be found in the distribution of literary tastes. Professional people are most strongly oriented to a high culture of classical authors, contemporary novels, and biographies, while manual workers, if they read at all, opt for books on gardening, sport, and leisure. Employers and the self-employed are different again, occupying something of a middle ground, but some of these variations are markedly influenced by the gender composition of these classes. Third, there are clear patterns in the relation between class standing and musical preferences, so that those of higher rank opt for 'high brow' genres (classical music, opera, and the like) with manual workers opting for country and Western music. The distribution of musical tastes across the board, however, is more complicated than a straightforward elite-mass distinction. Bennett et al. (2001) found that all classes nowadays prefer the middle-brow form of 'easy listening,' and pop and rock music, which leads the sociologists to propose a novel distinction between omnivores and univores. The former have musical preferences which cut across these boundaries of taste, the latter are much more restricted. At the end of the day, the explanation of these and other cultural tastes consistently turns on the level of education attained by those of different rank, for it is the extent of knowledge about the variety of available genres which opens up a broad field of choices.

Sociological findings such as these are useful to exploring the fine distinctions which constitute and compound the heterogeneity of the Australian middle classes; they raise significant questions about the relation between the knowledge classes, government funding, and the reproduction of economic and social inequalities into the next generation. At the same time, apart from a marked degree of predictability in their findings, a common failure is to leave out of the equation the most important of all middle-class resources, namely the private domestic properties around which revolve many of the securities and insecurities of middle-class existence in twenty-first-century Australia. Domestic property prices in the major metropolitan areas are now among the highest in the world: mortgages and rental payments consume an increasingly substantial percentage of two-income households, which is the norm. It is hardly surprising, then, that commercial television programs centered on home improvement strategies are astonishingly popular: indeed, their close reading might tell us considerably more about the fetishisms focused on the family home than any sociological survey of cultural choices.

The other weakness of analyses based on sociological surveys is that their findings are rarely integrated with broader transformations in the political economy of Australia, above all its relations with its global trading partners. This is, however, an increasingly pressing requirement where the interests and the investments of the more cosmopolitan knowledge classes are concerned.

The crucial development by far has been the emergence of China as Australia's major commercial partner, for this has repercussions across the Australian landscape, including its class structure and the distribution of power. The main factor in this equation has been China's near-insatiable demand for the raw materials of industrial production on the one hand and the ability of Australia's resource sector to meet much of it on

the other. Coal remains the country's main mineral export: Queensland alone provides one-third of the world's coking coal, which is needed to produce steel. Oil production is currently worth about AUD$30 billion each year, although, as this declines, its contribution to the economy is being overtaken by gas from Western Australia. The major source of iron ore is now the Pilbara region of Western Australia: the ore's high quality ensures that it is important to China's vast building program and industrial expansion. As is often remarked, the tyranny of distance in the past between Australia and the major marketplaces in the northern hemisphere has been turned on its head nowadays by the Antipodean advantage of proximity to Asia. The vast movement of commodities has been accompanied by the extensive mobility of people, including tertiary-level students and well-heeled middle-class tourists from China (in 2012, 70 000 and 550 000, respectively).

Inside Australia, the effects of these transformations in political economy have been wide-ranging. The first has been changes to regional economies of significance, so that while, for example, the renowned Iron Triangle of South Australia, once one of the country's major areas of industrial production, inexorably slides into decline, the Pilbara to the country's northwest is fast consolidating its position as the foremost region of capital investment and profit accumulation. Elsewhere, in New South Wales and Queensland, rural areas well-known for high-quality agricultural production and winegrowing are being bought out by transnational corporations for the extraction of coal and coal seam gas destined for export. The scale of some of these extractive enterprises is exceptional. The strikingly named China First Coal Project in Queensland, for instance, requires a single mining lease extending over some 21 561 km^2, which means that it is larger than the Northern Territory's internationally renowned Kakadu National Park, the largest national park in the country (Cleary, 2012: 17).

The second major impact involves changes to the upper reaches of the class structure. At one level, the nature of this is conspicuous enough in the emergence of a new plutocracy of resource entrepreneurs whose prosperity firmly locates them in the upper ranks of wealthy people at the global level. Ownership of the key means of twenty-first-century industrial production is often matched with an interest in the control of select media, which ensures that they become the focus of the public gaze. Far less easy to specify is the extensive stratum of senior managers, finance advisors, lawyers, accountants, major shareholders, and the like whose authority and influence is heavily reliant on the success of this new plutocracy, or more precisely the mobility of capital which is so integral to their power across the nation state.

Mobility is also key to the emergence of a new labor aristocracy of foremen, supervisors, and highly skilled workers, whose incomes and life styles on the one hand set them apart from the bulk of Australia's unionized workforce, but on the other hand lay down benchmarks for remuneration and conditions of employment to which many others can only aspire. As with the labor aristocracy brought into being by the first industrial revolution in Europe, spatial and social mobility is integral to the significance of this growing labor elite, as indexed by the novel FIFO label which has entered the national vocabulary. This refers to 'fly in–fly out' workers who reside in metropolitan cities or regional towns, and are flown to mining locations or oil fields for intensive periods of work while living in basic accommodation. Mining and oil companies see this as a flexible employment arrangement that obviates the need to build company towns, which was the pattern in the 1980s and resulted in 'ghost towns' once the resource was fully extracted. The costs to family and community life which this change involves are little understood, but companies are assuredly prepared to pay exceptional wages in order to exploit and to retain the high-level skills of these employees.

The Middle Classes and Australia's Environmental Crisis

Undoubtedly the most important impact of the 'resources boom,' however, has been the shielding of the mainstream middle classes from the global financial crisis (GFC) of recent times. It is certainly the case that the rate of economic growth in Australia has declined and that the value of some property in major cities and towns has depreciated. By contrast, however, with comparable classes in the northern hemisphere, Australia's middle classes have been able to sustain the high levels of conspicuous consumption to which they were well accustomed by the late twentieth century. This serves to underscore the paradox of the regional political economy in which the country is now inexorably locked: its material prosperity is inseparable from the economic underdevelopment, especially the availability of cheap productive labor, which characterizes its east and southeast Asian trading partners.

In other words, there has been no compunction for these affluent classes to reevaluate the patterns of overconsumption which are now widely acknowledged elsewhere as integral to environmental crises at regional and global levels. A number of surveys have indicated that people are apprehensive, even anxious, about the country's dependence on China as by far the most dominant force in the regional political economy, and this public concern spikes when especially iconic companies or sectors of production are acquired by the Chinese government, or its representatives. Thus, at the time of writing (September 2012), a major debate has broken out as to whether a Chinese textile consortium, Shandong RuYi, should be allowed to purchase a vast irrigation system in Queensland which, as part of the ailing Murray-Darling river system, has the capacity to produce over 10% of the country's entire cotton output. In such instances, the rhetorical terminology of 'the national interest' is parlayed from all possible angles, albeit without much by way of clear resolution. By contrast with such debates over productive resources, however, the excessive consumption patterns endemic to the middle classes receive little critical attention. Overconsumption is normalized and regularized to an exceptional degree in Australia, and the shielding of the middle classes from the most important negative impacts of the GFC has made it all the more so.

This omission is the more notable because the subject of environmental crisis is among the more significant threads running through the national political discourse. A number of environmental issues have been debated at the national level for many years, for example, the logging of old growth forests for woodchips, while others have emerged much more

recently, for instance, the spread of 'fracking' by exploratory companies referred to earlier. To a varying extent, such issues have provoked the spread of recurrent, even widespread, protest activity, and significant environmental gains have been recorded. But these localized activities only involve a small percentage of the population directly, and this has always been the case. For most middle-class Australians, their involvement has ranged from being vicarious to disinterested. The focus has rather been on expressing their environmental concern by spending more rather than less, of purchasing additional 'green' commodities – from organic foodstuffs through hemp-derived clothing to electric-powered vehicles – on top of those customarily consumed in the typical, prosperous, two-income household.

In short, the idea of seriously reducing expenditure and consumption remains quite alien: a fairly typical attitude seems to be that, if using low-energy light bulbs or sorting out the household waste into different containers is all that is necessary, high consumer middle-class existence can proceed as normal. Furthermore, if societal-scale environmental initiatives undertaken by government might increase the cost of living, the middle classes expect to be fully compensated rather than shoulder even a modest burden. There has been no better illustration of this belief, in combination with the new dominant class interests described above, than the public response to an initiative in 2012 by the Labor government to impose a carbon tax on the country's worst 500 polluting corporations. Since Australia is at the head of the global league of developed nations in terms of atmospheric pollution per capita, this was a progressive move, and when it was first mooted public opinion was generally supportive. When it became clear, however, that the carbon tax might result in even very modest increases to the average household budget, a sustained campaign underwritten by the major mining corporations that now dominate the industrial sector had little trouble in turning public opinion against the initiative, which then had to be significantly watered down.

Conclusion

The specifics of social and cultural relationships inside Australia have always been inseparable from changes to its broader political economy. Whether it is hybrid ethnic relations or involved class relations that are under the microscope, all are to some extent or other the product of Australia's high level of integration into its regional context and the global marketplace beyond. While materially prosperous and politically stable, as an ex-colony this nation state has throughout wrestled with the cultural uncertainties generated and sustained by economic dependency. There is no doubt that their specific character, and the politics which they generate, will be markedly different to those of earlier times.

Authentic Leadership

William L Gardner and James D Carlson, Texas Tech University, Lubbock, TX, USA

Abstract

Authentic leadership is a pattern of leader behavior that includes self-awareness, balanced processing of information, relational transparency with followers, and an internalized moral perspective. Authentic leader–follower relationships arise when both leaders and their followers remain true to their inner thoughts, beliefs, and experiences. Empirical research has established positive relationships between authentic leadership and positive individual (e.g., engagement, job satisfaction, job performance), group (e.g., teamwork), and organizational (e.g., financial performance) outcomes.

People who lead others while enacting their true selves, rather than a fake or distorted self, are said to engage in authentic leadership. The construct of authentic leadership has been formally defined as a pattern of leader behavior that includes self-awareness, balanced processing of information, relational transparency with followers, and an internalized moral perspective. Within the context of an authentic leader–follower relationship, both leaders and their followers remain true to their own inner thoughts, beliefs, and experiences. Empirical research on authentic leadership has established positive relationships between authentic leadership and many positive individual (e.g., engagement, job satisfaction, job performance), group (e.g., teamwork), and organizational (e.g., financial performance) outcomes.

Historical Overview

Scholarly and practitioner interest in authentic leadership has grown rapidly over the past decade, spurred on by a mixture of economic and societal forces. Particularly influential have been a series of shocks to the world economy, including the global financial crisis of the late 2000s. In attempting to discern the cause of the crisis and develop an understanding of how to prevent such events from occurring in the future, many have come to see leaders in various organizations as being partially culpable. For example, leaders of key US financial institutions authorized ethically questionable practices, such as securitizing subprime 'toxic' mortgages. Other leaders permitted investment or lending practices that were unacceptably risky, hampering responsible recovery when financial conditions worsened. While no one leader's actions alone caused this financial crisis, the cumulative ethical lapses of multiple leaders has been identified as a key factor that contributed to the financial meltdown. This is significant, considering the far-reaching impact of the crisis. Once the US economy fell into recession near the end of 2007, tightly interlocked global financial markets allowed for a chain of events that spread financial hardships throughout the world economy. Some have termed the resulting decrease in World GDP in 2009 as 'the Great Recession'. Today, many nations are still dealing with the effects of the financial crisis (e.g., the Eurozone).

For leadership scholars, the global financial crisis is just one example in a stream of modern events that have proven to be challenging for conventional leadership theories. That is, historically, leadership theories have not addressed what it means to be an authentic leader, or what the outcomes that accrue from such leadership might be. Research on authentic leadership has since helped to fill this gap in leadership theory and knowledge.

Early Conceptions

As with most new theories, initial attempts to explain authentic leadership took varied approaches. Given that current models of authentic leadership build on past research, understanding the history of the construct will help to place current authentic leadership theory and research in context.

An unusual aspect of authentic leadership theory is the fact that its growth and development coincides with the emergence of popular practitioner writings on the same subject. That is, popular works devoted to authentic leadership coevolved with the academic literature in the early 2000s, as practitioner interest in the topic contributed to scholarly interest, and vice versa. Key contributions to the practitioner literature include two highly popular books written by Bill George, the former CEO of Medtronic, titled *Authentic Leadership* (George, 2003) and *True North*: *Finding your Authentic Leadership* (George and Sims, 2007). Lauded by many for being a particularly authentic leader, George interviewed more than a 100 leaders in preparation for writing *True North*. He concluded that authentic leaders possess five important characteristics: (1) an understanding of their purpose; (2) clear and salient values with respect to doing the right thing; (3) a focus on trust in their relationships with others; (4) self-discipline in acting on their espoused values; and (5) a passion for their mission, enabling them to act from the heart. While evidence-based and well thought out, George's model is not intended to serve as a scientific theory.

Scholarly attention devoted to the study of authentic leadership began to rise shortly after the emergence of these practitioner approaches. The earliest theoretical model of authentic leadership development was proposed by Luthans and Avolio (2003). A key feature of this model was the inclusion of positive organizational behavior, which grew out of a movement toward positive psychology (Seligman and Csikszentmihalyi, 2000). Positive psychology emerged as a reaction to a persistent tendency in the field of psychology to focus on deficiencies and weaknesses, rather than on vitality and strengths. Research within the field of positive psychology therefore focuses on

understanding what promotes experiences of joy, happiness, and flourishing.

Luthans and Avolio (2003) suggested that authentic leaders influenced others by invigorating them through the activation of 'states' of positive organizational behavior. In contrast to the term 'trait', which refers to characteristics that are stable across contexts and resistant to change, 'states' can be developed and managed to achieve improved performance – an important implication for the development of authentic leadership. Subsequently, these positive organizational behavior states were subsumed under a more general, multidimensional construct called psychological capital, or PsyCap (Luthans et al., 2007). This construct incorporates the states of self-efficacy, optimism, hope, and resilience.

In their original model of authentic leadership, Luthans and Avolio (2003) suggested that the theory arose from the nexus of positive organizational behavior, transformational/full-range leadership development, and work on ethical and moral perspective-taking capacity. Authentic leadership was defined as "as a process that draws from both positive psychological capacities and a highly developed organizational context, which results in both greater self-awareness and self-regulated positive behaviors on the part of leaders and associates, fostering positive self-development" (p. 243). Moreover, they posited that such leadership worked when "[an individual is] true to him/herself and the exhibited behavior positively transforms or develops associates into leaders themselves" (p. 243). Thus, the mechanism of influence involved role modeling and arose from the leader's alignment of his or her behavior with core personal values and beliefs. As followers observed such behavior, they were often positively impacted by the leader and influenced to likewise align their values and actions. Such positive role modeling provides a stark contrast with other forms of influence, such as coercion, rational persuasion, or inspirational appeals that are rooted in personal leader charisma. Despite these differences, authentic leadership theory was thought to share some overlap with other forms of leadership. For example, Luthans and Avolio (2003) suggested that authentic leaders, like transformational leaders, tend to promote the leadership development of followers enabling them to become leaders themselves.

After the initial conceptions of authentic leadership were introduced, several refinements to the definition and theory emerged. A particularly important event in the history of research on authentic leadership occurred in 2004 with the inaugural Gallup Leadership Summit, which resulted in two key sets of publications focusing on authentic leadership development: (1) a special issue of *The Leadership Quarterly* (Volume 16, Issue 3) the premier journal for leadership research; and (2) an edited volume of the *Monographs for Management and Leadership* (Gardner et al., 2005b). Following these publications, a coalescence of theoretical considerations occurred. It is now possible to identify seminal work by identifying the theoretical foundations underlying research into authentic leadership (Gardner et al., 2011).

Authentic Leadership Theory

In recent years, theoretical attention devoted to authentic leadership has coalesced around a perspective introduced by Bruce Avolio, William Gardner, Fred Walumbwa and colleagues (Gardner et al., 2005a; Walumbwa et al., 2008). In this section, the concepts and literature that are foundational to this perspective are examined to facilitate understanding of the theory's underlying assumptions. It is important to initially explicate the meanings given to terms used in authentic leadership research, which often differ from everyday colloquial usage. The components that lie at the core of authentic leadership from this perspective are then discussed.

In contrast to earlier work, authentic leadership is now thought to lie at the nexus of leadership, ethics, and positive organizational behavior (Walumbwa et al., 2008). The important aspects of these fields, as they relate to authentic leadership research, are reviewed below.

One fundamental assumption of authentic leadership theory is that authentic leadership constitutes the 'root construct' that underlies positive forms of leadership (Avolio and Gardner, 2005). This creates a special relationship between authentic leadership and other positive perspectives of leadership. Whereas other positive leadership theories (e.g., transformational leadership theory, ethical leadership theory, spiritual leadership theory, servant leadership theory) attempt to explicate a range of positive behaviors under a single theory, authentic leadership theory suggests that authenticity provides a foundation for and thereby enhances these forms of leadership. In other words, considering authentic leadership as a root construct means that being an authentic leader does not preclude one from engaging in another type of leadership. To the contrary, authenticity is seen as enhancing and complimenting transformational, ethical, spiritual, or servant leadership because it ensures such leadership is genuine. The resultant alignment between the leader's values, principles, abilities, personality, motives, and behavior helps the leader capitalize on his or her strengths and achieve internal consistency, and thereby fosters follower trust, leader well-being, and leader effectiveness (Gardner et al., 2005a). However, this only holds true for positive forms of leadership that are aligned with authentic leadership, rather than negative forms of leadership. That is, if the form of leadership is dysfunctional (e.g., abusive supervision, narcissistic leadership, personalized charismatic leadership), it is not commensurable with authentic leadership.

Authenticity

The construct of authenticity lies at the center of authentic leadership theory (May et al., 2003). Authenticity has been defined in a variety of ways. Some suggest that authenticity involves owning one's personal experiences, be they thoughts, emotions, needs, preferences, or beliefs (Harter, 2002). Authenticity can also be described as the degree to which one fulfills personal expectations and commitments promised to oneself. When one is authentic, one's true or core self is unobstructed in one's daily enterprise (Kernis, 2003). The notion of authenticity is also captured by the injunction to 'know thyself'. Within the authentic leadership literature there is an implicit assumption that to know one's self includes *acting* in accordance with that known self.

Literature on authenticity assumes that people make commitments to their self-identity (Kernis, 2003). The emotions experienced when these commitments are violated

contribute to feelings of inauthenticity, or the negative feelings associated with 'being fake'. In contrast, there are also positive emotional and cognitive consequences that accrue when one acts in accordance with one's true self. People are generally not considered to be completely authentic or inauthentic; rather, authenticity operates on a continuum, and it is therefore more accurate to refer to people as being more or less authentic (Avolio and Gardner, 2005). Relatively authentic individuals pay more attention and are more devoted to achieving congruence between their internal self-experience and how they interact with the environment. For example, authentic individuals are generally highly aware of their values, and are more likely to act in accordance with them.

Highly authentic individuals have been shown to experience higher levels of psychological well-being, enhanced feelings of engagement, and elevated performance (Harter, 2002). What happens when such a person takes on a leadership role is the basic focus of authentic leadership theory. Authenticity in leadership can be seen as a paradox of sorts. An authentic individual in a leadership capacity is nonetheless self-referential with regard to being true to him or herself. However, leaders, by definition, must have follower(s), and it is a key part of leadership to be aware of follower needs and circumstances. Part of the goal of authentic leadership theory is to explain why this paradox works, answering the question "how does being true to one's self elicit positive relational consequences and outcomes?"

Core Components of Authentic Leadership

Though authentic leadership is often oversimplified as involving an approach to leadership where one can 'be true to one's self', current theory suggests that authentic leadership goes beyond this foundational notion (Walumbwa et al., 2008). Indeed, authentic leadership involves more than being an authentic person since leadership is required. As the definition presented above suggests, authentic leadership involves a pattern of leader behavior. The four components of this pattern suggested by Walumbwa et al. (2008) are reviewed below.

Self-awareness

Leader self-awareness refers to a leader's understanding of how he or she derives meaning from the world, and how this meaning-making process impacts his or her view of the self and the world over time. This understanding includes the recognition of personal strengths and weaknesses, in addition to the many different facets of the self (some perhaps more likable, accepted, or desirable than others). Through interactions with others, leaders with high self-awareness gain valuable personal insights including knowledge about how they impact others in general, and especially those that they lead.

Internalized Moral Perspective

An internalized moral perspective refers to a leader holding and adhering to core ethical values, standards, and principles as an act of personal choice. That is, authentic leaders are driven by internal moral standards regardless of whether they match or deviate from prevailing norms of a group, organization, or social context. Indeed, an internalized moral perspective guides the leader toward decisions and behaviors that are congruent with their values, even in the face of environmental pressures, including rewards and sanctions, to do otherwise. In contrast, the moral conduct of extrinsically motivated leaders is easily swayed by external forces. The internalized moral perspective component of authentic leadership is really a form of self-regulation (Deci and Ryan, 2000). Because authenticity involves the unobstructed operation of one's true or core self, following one's inner sense of right and wrong is a fundamental element of authentic leadership. Hence, authentic leaders are not enticed by opportunities to get ahead that require violations of their core principles and commitments.

Other theories of leadership also specify an ethical component (e.g., transformational leadership; Bass and Avolio, 1994) or provide almost an exclusive ethical focus (e.g., ethical leadership; Brown and Trevino, 2006). Some view authentic leadership as diverging from these perspectives because they believe authentic leaders need not necessarily be ethical. However, Avolio and Gardner (2005) reject this notion. To the contrary, they assert that highly authentic leaders operate at a high level of moral cognitive development. That is, authentic leaders, like transformational leaders, pursue end values that prohibit knowingly engaging in unethical conduct.

Balanced Processing of Information

Leaders often operate at the nexus of various sources of information; as such, one of their key responsibilities is to process this information to make decisions. Balanced processing refers to the evaluation of ego-relevant information – be it favorable or unfavorable – in a relatively unbiased fashion. In addition, authentic leaders seek out objective information even if it challenges their preexisting notions. This is borne out of a sense of security that accrues for authentic persons. Indeed, when one understands and owns the self, including both strengths and weaknesses, one is more receptive to negative feedback that may be ego-threatening and hence subject to distortion for less authentic and secure persons. Balanced processing helps authentic leaders make the right decision for their group, organization, or society, even if doing so may not be personally beneficial. Thus, authentic leaders are open to feedback, in contrast to leaders who only want to hear good news.

Relational Transparency

Relational transparency involves the presentation of one's true self to close others (Gardner et al., 2005a). Organizations and other settings often provide opportunities and even incentives to manage impressions and manipulate relationships. Authentic leaders do not obfuscate their purposes or desires, and do not misrepresent themselves to achieve desired goals. Specifically, to the extent possible, authentic leaders disclose work-related information in a transparent and open fashion, as long as doing so does not violate the privacy or safety of others. In cases where full disclosure would be inappropriate, such leaders release as much information as possible, while communicating the reasons for not withholding certain facts. Relational transparency also refers to sharing one's true thoughts and feelings openly, while maintaining dignity appropriate to the workplace and context. Thus, followers understand the reasoning behind a leader's decision, which decreases fear of the unknown and fosters feelings of trust.

Theoretical and Empirical Antecedents and Outcomes

Consistent with their theoretical perspective, Walumbwa et al. (2008) found empirical support for a multidimensional, higher-order construct of authentic leadership comprised of the four basic components previously discussed. The emergence of a validated measure of authentic leadership, the Authentic Leadership Questionnaire (ALQ; Walumbwa et al., 2008), has stimulated research on the multicomponent model. More recently, an alternative and psychometrically sound measure based on the same four-component model, the Authentic Leadership Inventory, has been advanced (Neider and Schriesheim, 2011).

Authentic leadership has been connected to a variety of antecedents and outcomes, both theoretically and empirically (Gardner et al., 2011). While sensational examples of malfeasance provided the original impetus for understanding authentic leadership, it is now evident that the costs of inauthentic leadership can be great for any organization or team. Conversely, the benefits of authentic leadership have been found to be wide ranging and compelling. In this section, the major empirical findings relative to the theoretical antecedents and outcomes of authentic leadership are discussed.

Antecedents

As noted in Section Early Conceptions, early models defined authentic leadership "as a process that draws from both positive psychological capacities and a highly developed organizational context" (Luthans and Avolio, 2003: p. 243). More recently, however, models of authentic leadership see positive psychological capacities and positive ethical climate as peripheral antecedents and consequences, rather than core components of the construct. To date, research on the antecedents of authentic leadership has been very limited. While some support for PsyCap leading to authentic leadership has been found (Jensen and Luthans, 2006), this research was conducted before Walumbwa et al. (2008) operationalized the multicomponent model of authentic leadership through the introduction of the ALQ.

Outcomes

The majority of empirical work on authentic leadership has sought to explicate its outcomes, rather than its antecedents (Gardner et al., 2011). Many theoretical propositions regarding these outcomes have been supported. Indeed, this may be part of the reason why authentic leadership has sustained the attention of the scientific community. In this section, we briefly review some of the predicted outcomes and relevant empirical findings. Some outcomes are posited explicitly in models of authentic leadership, whereas others have been derived from those models.

Overall, the Gardner et al. (2011) review suggests that authentic leadership is associated with positive leader (psychological well-being), follower (empowerment, job performance, job satisfaction, organizational citizenship behaviors, organizational commitment, trust in leadership, work engagement, and work happiness), and organizational outcomes (openness of organizational climate and firm financial performance). Authentic leadership was also shown to be negatively associated with undesirable outcomes (e.g., follower burnout and contingent leader self-esteem). Together, these results provide evidence of predictive validity of the authentic leadership construct. Subsequent research provides additional empirical evidence of predictive validity, as authentic leadership has been shown to be positively related to behavioral integrity (Leroy et al., 2012b), perceived leader effectiveness (Moriano et al., 2011), follower extra effort (Moriano et al., 2011), satisfaction with the leader (Moriano et al., 2011; Neider and Schriesheim, 2011), follower basic need satisfaction (Leroy et al., 2012a), follower general satisfaction (Neider and Schriesheim, 2011), follower organizational commitment (Neider and Schriesheim, 2011), follower affective commitment (Leroy et al., 2012b), follower social exchange (Chiaburu et al., 2011), follower creativity (Chiaburu et al., 2011), follower work role performance (Leroy et al., 2012a,b), positive (Woolley et al., 2011) and collective psychological capital (Woolley et al., 2011), organizational citizenship behavior (Walumbwa et al., 2011), positive work environments (Walumbwa et al., 2011), group level performance (Woolley et al., 2011), firm level performance (mediated through top management team positive affective tone; Hmieleski et al., 2012), team trust (Walumbwa et al., 2011), team authenticity (Hannah et al., 2011), and teamwork behavior (Hannah et al., 2011).

Gardner et al. (2011) note that while the research to date is informative, much work remains to advance our understanding of authentic leadership. To do so, they recommend a five-pronged agenda for future research: (1) stronger theory building, (2) expansion of the nomological network, (3) more rigorous and diverse methods, (4) attention to authentic followership, and (5) attention to authentic leadership development. In a separate review of the leadership literature, Avolio et al. (2009) came to a similar conclusion that the measurement of constructs relating to authentic leadership is at an early stage of development. They identify several relevant constructs that have not yet been examined, such as moral perspective, self-concept clarity, psychological well-being, spirituality, and judgment. They also suggest that additional research is needed to examine authentic leadership across different cultural and situational contexts.

One way that the theory building can be enhanced is by more clearly articulating the boundary conditions. Though the intent of research behind authentic leadership is to understand a wide range of phenomena, it is likely that some contexts are not fully supportive of authenticity and authentic leadership (e.g., toxic organizational cultures). While some work on boundary conditions of authentic leadership has been done (Eagly, 2005), more theory and empirical research is needed to explicate these boundaries.

Another area that requires greater research is the interplay between authentic leadership and authentic followership. In their initial conceptualization of authentic leadership, Gardner and associates (Gardner et al., 2005a) posited a parallel process to authentic leadership whereby followers come to function authentically, in part by modeling the authenticity of the leader. In their review of the literature, Gardner et al. (2011) pointed out that the role of authentic followership within authentic leader–follower relationships had not been examined, despite it being a crucial component of authentic

leadership theory. In an initial step toward filling this void, Leroy et al. (2012a) demonstrated that work units that were characterized by relatively high levels of authentic leadership provided a supportive context for followers' satisfaction of their basic needs for autonomy, competence, and relatedness, and thereby fostered authentic followership and elevated levels of follower work role performance. Moving forward, additional research is required to explore the role that authentic leadership plays in facilitating follower authenticity at work, as well as the extent to which authentic followership in turn enables leaders to achieve authenticity.

Authentic Leadership Development

As authentic leadership theory continues to evolve, some have recommended that the field pay greater attention to authentic leadership development (Avolio et al., 2010). As discussed earlier, authentic leadership development was the primary concern of some of the earliest models of authentic leadership. This focus may have arisen from the initial impetus for learning about authentic leadership (e.g., corporate malfeasance) and a desire to change what was perceived as a societal trend toward the development of inauthentic leaders.

Some scholars have cautioned that we face many challenges in developing authentic leaders (Cooper et al., 2005), while others have advocated in favor of such development (Avolio and Gardner, 2005). A recent review of authentic leadership development (Avolio, 2010) traces the personal experiences of Bruce Avolio, who has been on the front lines of authentic leadership development research. Investigations into authentic leadership development ask whether leaders are born or made, and whether leaders can be changed by experienced planned interventions. In addition, models of authentic leadership development include trigger events, self-reflection, and developmental readiness, as well as core components of authentic leadership theory. Avolio et al. (2010) note that the future of authentic leadership development will likely incorporate more consideration of contextual influences, as much of the focus on training and development of authentic leaders has taken place outside of the context where they work. One way to better explicate the work context would involve embedding leadership training into organizations internally (rather than addressing the need by using an external source, such as a leadership consultant).

Conclusion

Despite being a relatively new construct, authentic leadership is a popular approach to understanding leadership for both academics and practitioners. It emerged as interest in genuine, veritable leadership increased. The foundation for authentic leadership stems from the attainment of individual authenticity on the part of the leader. For authentic *leadership* to be achieved, however, a pattern of leader influence that consists of high authenticity relative to followers is required. In other words, authentic leadership occurs when leaders achieve high self-awareness, balanced processing, relational transparency, and an internalized moral perspective in their relationships with followers. Authentic leadership has been theoretically and empirically related to many desirable outcomes. While many additional questions remain to fully develop and assess the theory, it is evident that authentic leadership has captured the attention of researchers and practitioners due to its potential utility in fostering positive and sustainable individual, group, and organizational outcomes.

Authenticity, Anthropology of

Richard Handler, University of Virginia, Charlottesville, VA, USA

Abstract

The anthropology of authenticity concerns the relationship of cultural objects and processes to posited social or cultural identities. From an objectivist perspective, it should be possible to validate such assignments of identity; from a constructionist perspective, identity-making is an ongoing social and political process that is often contested, yet also central to the cultural aspirations of many of the people anthropologists study.

Within anthropology, there are two principal approaches to the question of authenticity. The first presupposes that authenticity is an attribute or property inherent in cultural objects, and that the role of anthropology is to determine, using scientifically appropriate evidence and methods, whether particular objects are or are not authentic. The second locates authenticity not in objects but in discourses about them. This approach holds that the authenticity of phenomena is never a matter of objectively determinable fact, but is always socially constructed and, as such, subject to change.

Presently, the second approach is in the ascendance. It would, however, be short-sighted to view this trend as the culmination of a unilineal historical development in which the second approach has eclipsed the first. Rather, these opposed approaches endure because they replicate a fundamental epistemological opposition within modern societies, that between objectivism, realism, or positivism, on the one hand, and constructionism or hermeneutics, on the other. Despite the recent persuasiveness of constructionism in social science, objectivist notions of authenticity remain hegemonic in many late-capitalist institutions, such as the art market, museums, and courts of law.

Authenticity and Reality

Questions about authenticity should be distinguished from questions about reality and its representation. To ask whether an object is real, or an event occurred, is to ask about its existence relative to the empirical world. To declare an object or event 'unreal' or 'illusory' is to claim that it never existed or occurred. Note that such 'unreal' phenomena can exist in imagination. At least since Durkheim, anthropologists have argued that representations of objects are real-world phenomena with real-world effects, whether or not the objects of such representations can be shown (according to some sets of criteria) to exist in the world beyond those representations.

In contrast, to ask whether an object is authentic is to ask not about its existence but about its relationship to a posited social or cultural identity. The opposite of 'authentic' is not 'unreal' but 'inauthentic.' To deem an object inauthentic is to assert that it is not, despite claims to the contrary, an example of an identified class of objects, or not the creation of an identified person or group.

It is easy to confuse questions of reality and those of authenticity due to the commonsense use of the word 'real' to mean 'authentic,' as in the phrase 'this is a real Native American medicine bundle.' Such claims are not intended as predications of existence as such, but as evaluations of what is understood to be the essential nature, or the identity, of the phenomenon in question. Thus, assertions of authenticity always have embedded within them assertions of identity.

Throughout the history of their discipline, anthropologists have been asked to authenticate artifacts, customs, legends, texts, and other cultural objects, as well as the racial, ethnic, or cultural affiliation of persons. Depending on subdisciplinary and areal expertise, anthropologists might offer authoritative answers to such questions as: 'Are these stone weapons Clovis points, from Western North America and 12 000 years old, or are they modern reproductions?' 'Can this narrative be attributed to precolonial Native Americans, is it the result of European influence on Native American traditions, or is it a recent creation, and if the latter, what is the cultural identity of its author?' And most bluntly: 'Are these people Indians with unbroken ties to precolonial America, or have generations of racial mixing and cultural borrowing erased that identity?' Such assessments of the authenticity of particular objects and persons are similar to those required in fields like art history and museology, where it is often important to be able to identify objects by attributing them to named artists, historical periods, or cultural groups.

Authenticity and Modern Individualism

The commonsense notion that authenticity is an expression of the essential identity of an object stems from modern (in the sense of post-fifteenth century) individualism. In this worldview, ultimate reality is understood to be lodged, not in a hierarchically interrelated divine cosmos, but in individuals, from the smallest particles to persons to delineated groups of persons (cultures). To quote the philosopher Cassirer on the modern ontology of nature: "Nature…implies the individuality, the independence and particularity of objects. And from this characteristic force, which radiates from every object as a special center of activity, is derived also the inalienable worth which belongs to it in the totality of being… The part not only exists within the whole but asserts itself against it, constituting a specific element of individuality and necessity" (1965, p. 41).

From such an outlook the notion of authenticity derives: each object, each individuality is itself a center of reality with a unique essence or identity that distinguishes it from all other objects.

Authenticity and Sincerity

In *Sincerity and Authenticity*, Trilling (1972) drew out the implications of this worldview for modern conceptions of sociality and personhood. With the emergence of modern individualism, persons were no longer defined by their position in a social hierarchy (as in medieval European realms). Instead, social positions came to be understood as 'roles' to be filled by persons whose essence, or individuality, precedes and transcends those roles. In this perspective, the inner realm of individual character or personality is more real than the outer world of social relations.

The importance of sincerity in the early modern period, Trilling argued, derived from concerns about whether a person's social actions matched or masked inner attitudes. Indeed, it was insincerity that was at issue. As Rousseau puts it, humans in the 'state of nature,' prelingual and presocial 'savages,' had no means to dissemble; their actions could be nothing other than the direct expression of their inner or essential being. But with the emergence of human language and society, "it…became the interest of men to appear what they really were not" (1973, p. 86). Inner authenticity diverged from outer sociality, and the 'rise' of civilization, as Rousseau saw it, entailed a process of moral corruption.

In Trilling's account, concern for sincerity, with its questioning of the relationship between society and the individual, began to cede place in the Romantic period to concern for authenticity, which privileges inner essences without relating them to an outer world of other people. The Romantics' quest for authenticity was a quest for 'essential identity,' a longing for knowledge of true inner being irrespective of any accidents of social history or circumstance. Artists, in particular, were understood to be individuals possessed of powerfully unique inner realities, uncorrupted and undiminished by social conventions. At the same time, the growing middle classes of the new mass democracies were coming to see their lives or identities as increasingly 'unreal' or 'inauthentic.'

Authenticity and Collectivities

In social philosophy, and later the social sciences, these concerns for individual realities were applied to human collectivities. The leap from the individual to the collective is not as great as it seems, for, as Dumont (1970) has insisted, modern ideology understands groups as 'collective individuals.' From the eighteenth century onward, folklorists and anthropologists assumed that groups of people could be characterized by unique cultural, historical, religious, linguistic, or otherwise traditional features that set them off from all other groups. These models of the group were often naturalistic, using analogies to biological organisms or species: it was assumed that a group was a bounded natural unit or object, that members of the group shared its defining features, and that it was possible objectively to evaluate the cultural identities of individual persons, based on the cultural attributes they 'possessed.'

Authenticity Endangered

A noteworthy accompaniment of this conception of cultural authenticity is a fear of its demise. Authenticity is seen to be perpetually threatened. The authenticity of nonmodern ('savage,' 'primitive,' 'native,' 'indigenous,' 'folk,' 'peasant,' or 'traditional') cultures is imagined to depend on their pristine existence beyond the reach of advancing 'civilization.' Throughout the epoch of European colonial expansion, down to the present day, metropolitan authorities – scholars, travelers, missionaries, colonial officials, collectors – took it upon themselves to delineate unique groups in terms of their 'possession' of specific racial, linguistic, and cultural attributes. The impingement of European culture on such groups, or even the influence of non-European but purportedly more 'complex' cultures, was thought to alter their unique identities and thus to destroy their cultural authenticity. Such conceptions were applied at the level of the individual as well, such that in colonial social orders, the 'half-breed' (to use a racial term) or the culturally bastardized colonial subject was often scorned as the embodiment of the worst of both the 'primitive' and 'civilized' worlds.

In sum, the European 'discovery' of 'Others' followed by ongoing 'contact' made them, almost by definition, inauthentic. Authenticity as a quality of cultures, artifacts, and persons was projected by metropolitan authorities into the past, a past they might be able to document, but only just before its destruction.

Constructionist Accounts of Authenticity

Despite the pervasiveness of such assumptions about groups as bounded objects, there have been recurring social-scientific trends (historical diffusionism, for example) that privileged intergroup connections, contacts, borrowings, and syncretisms. In Anglo-American anthropology since the 1970s, there has been growing rejection of the notion that cultures, societies, and groups in general are naturally bounded and internally homogeneous. Indeed, it is now commonplace to assert the opposite, and to claim that groups are historically and situationally contingent; that the relative rigidity (or porousness) of group boundaries is a function of semiotic, not natural, factors; that collective identities salient in contemporary institutions, politics, and scholarship ought not to be projected into the past; that individual persons have multiple identities that can shift according to social context, although not without regard to institutional and cultural constraints; and that the products of human creativity cannot unproblematically be assigned cultural, racial, or ethnic identities. In addition, recent historical scholarship has argued that the work of colonial cultural classification was carried out in areas of the world where European notions of objective social boundaries encompassing homogeneous, authentic cultural identities made little sense in relation to local people's understanding of sociality.

Negotiating Authenticity

Constructionist approaches to authenticity question whether it is useful to specify the 'essential' identity of groups, artifacts,

and persons. Since human beings are historically and socially situated, they are always connected to other people. Culture exists not simply *in* them but *between* them. Any understanding of a particular person's or group's authentic identity will be a function of specific social encounters, and particular evaluations of authenticity are open to negotiation and dispute. An 'expert' (colonial administrator, art collector, anthropologist) may claim that a person is not a 'real' or 'pure' member of a posited culture, or that an artifact is not an authentic product of it, but others may reject such evaluations based on differing definitions of cultural boundaries and essences.

This does not mean it is impossible or unhelpful to describe and classify cultures. Rather, it means that the terms used to do so must be understood in relation to the discursive project of the classifiers. At any historical moment, some such terms will be relatively unproblematic. For example, given our present technology and understanding of time, we can expect the carbon 14 dating of archaeological artifacts to yield valid information. We need not question the empirical validity of the description to recognize that such data become useful, or meaningful, only in terms of more general hypotheses concerning culture history, hypotheses that can never be reduced merely to facts derived from carbon 14 dating. Moreover, terms of cultural classification that are unproblematic in one context might become contested in another, for example, present-day descendants of precolonial Native Americans might dispute carbon 14 results, claiming a greater antiquity for artifacts than anthropological methods can demonstrate.

The Politics of Authenticity

Assertions of cultural authenticity can have political consequences. Among the most serious are governmental recognition of 'tribal' or 'aboriginal' status, a status that often entitles group members to government subsidies and services, and to government (mis)management. In settler societies such as the United States, Canada, and Australia, some 'indigenous' groups have governmental recognition based on treaties, some of which date to the late eighteenth century; other groups claiming to be authentically indigenous may turn to the courts to gain such recognition. In the courts, authenticity is defined in terms of temporal continuity, cultural homogeneity and distinctiveness, and geographical stability. It may or may not be possible for people who have lived for generations in a situation of 'contact' to demonstrate possession of cultural authenticity defined in such terms. Indeed, there is a cruel irony inherent in the relationship of 'native' authenticity to nation-state citizenship. On the one hand, 'indigenous' peoples are asked to assimilate, through education and economic mobility, into modern society; on the other hand, to do so is to be seen as having become inauthentic and to be scorned on that basis. In practice, both racist barriers and modern fantasies of authenticity fence people in, making it difficult for them to enjoy full citizenship.

Claims concerning the authenticity of individuals and objects can also have political (and economic) consequences. Government criteria to evaluate the affiliation of individuals to recognized tribal groups are often based on quantifications of 'blood'; that is, proportion of 'native' descent. Such criteria usually do not match those that defined social inclusion before the imposition of modern definitions of authentic personhood. Individuals' access to government benefits nonetheless depends upon satisfying the imposed criteria.

The authenticity of cultural objects is negotiated in the markets for art, museum artifacts, and touristic souvenirs. Objects deemed culturally authentic command higher prices and can claim space in more prestigious venues, such as museums and the homes of wealthy collectors, than those considered culturally 'mixed' or 'commercial.' Over time, however, objects can gain authenticity as scholars and collectors objectify and historicize what were once seen as debased cultural forms. 'Indigenous' artists and craftworkers, too, can influence standards of authenticity as they position themselves vis-à-vis the art market and museum world.

Indigenous Control of Authenticity

At the beginning of the twenty-first century, political trends and technological developments have combined to give indigenous peoples around the world renewed control over what they considered to be their own cultural property. The global expansion of intellectual-property laws and United Nations' declarations supporting indigenous cultural-property rights have led many national governments to revise their property regimes, in dialogue with indigenous peoples living within their territories. At the same time, anthropologists, museum directors and curators, art and antiquities dealers, and private collectors have been brought, willingly or otherwise, into dialogue with newly empowered indigenous groups seeking either the return of cultural property (from museums, for example, to tribal institutions) or increased access to it. In practice, this has meant that indigenous peoples, anthropology's traditional object of study, have gained new leverage to participate in debates about authenticity. As objects begin to circulate in new ways – for example, nineteenth-century artifacts might be returned to the descendants of the people who created them, to be used in contemporary religious or cultural activities – their cultural authenticity is renewed and redefined.

At the same time, digital technologies are creating new ways to access stationary cultural properties. Museums, for example, now digitize their collections, allowing visitors to view aspects or images of objects not available in standard displays. Local or indigenous institutions can choose to have items of cultural property exhibited and/or protected in metropolitan institutions while making use of digitized images and digital databases for use in their communities.

Whether new legal regimes and new technologies will lead to changes in concepts of authenticity remains to be seen, but it is already clear that they have opened the debate to new participants. Anthropologists will continue to play an important role as scholars and even arbiters of authenticity, but going forward, we may as often be employed by indigenous communities seeking to define authenticity in relationship to their own ideas and goals as by metropolitan universities and museums seeking to protect theirs.

Authoritarian Personality

John Duckitt, The University of Auckland, Auckland, New Zealand

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The theory of an authoritarian personality was an influential though controversial mid-twentieth-century theory to explain the mass appeal of fascism and ethnocentrism. Methodological and conceptual criticisms of the original theory, however, lead to alternative theories and culminated in research suggesting two distinct dimensions of ideological attitudes, Right-Wing Authoritarianism (RWA) or Social Conservatism and Social Dominance Orientation (SDO) or Anti-Egalitarianism. RWA and SDO were initially thought to be direct expressions of two different authoritarian personalities, but have more recently been seen as describing social or ideological attitude dimensions with multiple social and personal determinants.

The idea of an authoritarian personality emerged in the 1930s as an attempt to explain the popular appeal of fascist movements, such as the Nazis, in many European societies. At that time, European philosophy and social science was strongly influenced by Marxism, and a major prediction from Marxism was that the crisis engendered by the Great Depression should radicalize the working classes and lead to socialist revolutions. This expectation, however, was confounded in much of Europe where the crisis did not produce socialist revolutions but resulted in mass support for fascist movements advocating authoritarian leadership and virulent anti-Semitism. The explanation proposed was that a particular kind of authoritarian personality, which had become socially widespread, would under threatening conditions make people emotionally and cognitively vulnerable to the appeal of fascist ideologies and to ethnocentric hostility to vulnerable minorities.

Reich (1975), for example, argued that capitalist social structures were characterized by punitive families, which used child-rearing practices involving extensive sexual repression to create authoritarian personalities, who would be unlikely to rebel against exploitative social conditions and yearn for powerful leadership. This authoritarian character structure was described as conservative, afraid of freedom, submissive to authority, obedient, yet with 'natural aggression distorted into brutal sadism' (p. 66). Maslow (1943) and Fromm (1941) produced similar descriptions of an authoritarian personality to explain the appeal of fascist movements and ideologies.

These early theories were speculative and did not develop empirically based measures of their constructs. As a result, they produced little research. However, their core idea that social and ideological beliefs are a direct expression of basic needs in the personality did later prove highly influential and dominated much of social scientific thought and theory about the psychological bases of ideology and prejudice for much of the rest of the twentieth century.

Original Theory of the Authoritarian Personality and the F Scale

It was in 1950 with the publication of a classic volume titled *The Authoritarian Personality* that these ideas finally became prominent in the social sciences. In this volume the authors (Adorno et al., 1950) theoretically elaborated a theory of the authoritarian personality and reported the results of a multi-pronged decade-long program of research testing the theory. Their investigation had begun with the objective of explaining the psychological bases of anti-Semitism. This was shown to be part of a much broader ethnocentric pattern involving a generalized dislike of out-groups and minorities, as well as an excessive and uncritical Nationalism. Anti-Semitism and ethnocentrism were also strongly related to political and economic conservatism. These attitudes and beliefs appeared to cluster together to form a coherent pattern, and this patterning seemed best explained as an expression of basic needs within the personality.

Evidence from a number of sources and particularly their own research comparing persons high and low in ethnocentrism on indices and ratings scored blind from interview data, and projective test protocols suggested that a constellation of nine tightly covarying traits characterized this authoritarian personality syndrome. Moreover, these traits seemed to be directly expressed in particular 'implicitly antidemocratic,' or authoritarian, attitudes and beliefs. This meant that it would be possible to identify authoritarian personalities by the degree to which people would agree with these 'implicitly antidemocratic' attitudes and beliefs. On this basis, Adorno et al. (1950) developed their famous F scale consisting of items expressing attitudes which were believed to be direct expressions of each of the nine 'traits' of the authoritarian personality syndrome. These nine 'traits' are listed below with their gist definitions in parentheses followed by an example in quotation marks:

- *Conventionalism* (rigid adherence to conventional middle-class values): "A person who has bad manners, habits, and breeding can hardly expect to get along with decent people."
- *Authoritarian submission* (a submissive, uncritical attitude toward authorities): "Obedience and respect for authority are the most important virtues children should learn."
- *Authoritarian aggression* (tendency to condemn, reject, and punish people who violate conventional values): "Homosexuals are hardly better than criminals, and ought to be severely punished."
- *Anti-intraception* (opposition to the subjective, imaginative, and tender-minded): "Nowadays more and more people are

prying into matters that should remain personal and private."

- *Superstition and stereotypy* (belief in mystical determinants of the individual's fate, disposition to think in rigid categories): "Some day it will probably be shown that astrology can explain a lot of things."
- *Power and toughness* (preoccupation with the dominance–submission, strong–weak, leader–follower dimension; identification with power, strength, toughness): "People can be divided into two distinct classes, the weak and the strong."
- *Destructiveness and cynicism* (generalized hostility, vilification of the human): "Human nature being what it is, there will always be war and conflict."
- *Projectivity* (disposition to believe that wild and dangerous things go on in the world; the projection outward of unconscious emotional impulses): "Most people do not realize how much our lives are controlled by plots hatched in secret places."
- *Sex* (an exaggerated concern with sexual 'goings-on'): "The wild sex life of the old Greeks and Romans was tame compared to some of the 'goings-on' in these regions, even in places where people might least expect it."

Adorno et al.'s (1950) theoretical explanation for the origin of this authoritarian personality drew heavily on psychodynamic theory. It suggested that overstrict, harsh, and punitive parental socialization sets up an enduring conflict within the individual. In this conflict, parental punitiveness engenders resentment and hostility toward parental authority and by extension all authority, but cannot be expressed because of fear of and dependence on the all-powerful parents. The anger and hostility are therefore repressed and replaced by an uncritical idealization of the parents and conventional authority and submission to them. The repressed anger and hostility toward authority does not disappear but is displaced and directed toward substitute targets, notably those seen as being sanctioned by conventional authority, such as vulnerable and culturally deviant out-groups and minorities. These inner impulses and conflicts are then directly expressed in the nine surface trait components of the authoritarian personality and those implicit antidemocratic beliefs sampled by the F scale.

Initially, this theory inspired a great deal of enthusiasm. It seemed to effectively tie together concepts over an extremely broad range – from individual psychodynamics to sociological phenomena of immense significance for human society and history. In the two decades following the publication of their book, the F scale was used in hundreds of studies as a measure of an authoritarian personality dimension. These studies confirmed that scores on the F scale were strongly correlated to right-wing attitudes, political conservatism, nationalism, and generalized prejudice against out-groups and minorities (see, e.g., the review by Brown, 1965).

Critical Reaction to the Original Authoritarian Personality Theory

Adorno et al.'s (1950) theory and research, however, also generated a great deal of criticism (see, e.g., Christie and Jahoda, 1954). First, subsequent research could not find clear support for the psychodynamic propositions of their theory. Second, much of their research validating the F scale, which compared high- and low-prejudice participants, seemed seriously compromised because of their failure to use blind ratings and control for sociodemographic and other group differences. Third, their theory and concepts seemed to explain only authoritarianism of the political right and ignored authoritarianism of the left. And, fourth, the F scale became a particular focus of controversy, because all its items were positively worded, so that agreement always indicated high authoritarianism, and disagreement low authoritarianism. One consequence of this was that acquiescence (or the tendency of people to agree rather than disagree) might influence scores on the F scale. A further and more serious consequence in psychometric terms was that acquiescence might have inflated or even caused the apparently high level of covariation between the items of the F scale. If so, the apparent reliability of the F scale might be spurious and it might not be measuring a single personality trait dimension after all.

Most critics did feel, however, that despite its flaws, the two most basic tenets of the theory were valid. These were the assumptions that social attitudes and beliefs were meaningfully organized along a single broad ideological dimension and that these attitudes were direct expressions of personality. A number of subsequent studies therefore focused on trying to remedy the weaknesses of Adorno et al.'s (1950) original research. One important goal of this research was to try and 'balance' the F scale, that is, to produce an F scale that would contain equal numbers of pro- and anti-authoritarian items so that the total scale score would not be influenced by acquiescence. These attempts generally failed with the resulting balanced F scales having very low internal consistencies, that is, the items simply did not correlate sufficiently strongly to indicate that they were measuring a single unitary syndrome and therefore could not be expressive of a particular personality dimension (see, e.g., Altemeyer, 1981). Most researchers on the topic were reluctant to abandon such a core proposition of the theory and preferred to conclude that failure to develop adequately balanced versions of the F scale was because the nature of its items made it difficult to psychologically reverse their meaning. The alternative possibility that the F scale might simply be covering a range of item content that was not unidimensional was not seriously investigated until very much later.

The failure to balance the F scale and the many other criticisms of the original theory did also result in attempts to develop a better theory and measure of the authoritarian personality. These all shared the basic assumption of the original theory, which was that social attitudes in general were ideologically organized along a single dimension that was a direct expression of personality.

Alternative Theories of the Authoritarian Personality

In his book, *The Nature of Prejudice*, Gordon Allport (1954) described the kind of personality that would be generally prejudiced against out-groups and minorities, which closely followed Adorno et al.'s (1950) nine surface traits of their authoritarian personality. Allport, however, largely discarded the idea that these traits were the result of inner psychodynamic

conflict and instead proposed that they stemmed from personal insecurity and fearfulness, or 'ego weakness.' This personal insecurity and fearfulness, he suggested, would cause authoritarian personalities to need structure, order, and control in their social environments and to react with punitive hostility to social change, deviance from convention, and novelty. Allport did not develop a measure of his concept of the authoritarian personality so that his ideas never acquired prominence of those of Adorno et al. (1950), but his simplified conceptualization was broadly adopted by later theorists, such as Wilson (1973) and Altemeyer (1981) who did develop influential new measures.

A second reconceptualization was proposed by Rokeach (1954), who suggested that the core characteristic of the authoritarian personality was a rigid cognitive style, characterized by "a relatively closed cognitive organization of beliefs … organized around a central set of beliefs about absolute authority" (p. 195), which he therefore named Dogmatism. Persons high in dogmatism would be attracted to authoritarian movements and beliefs of either the political right or the left, and cause them to dislike and reject persons and out-groups with dissimilar beliefs and values to their own.

Rokeach (1960) developed a D scale to measure dogmatism, but it shared many of the flaws of the F scale. The items of the D scale did not seem to directly assess a cognitive style, but tended to be broad statements of opinion or social attitude that were often very similar to those of the F scale. Not surprisingly, therefore, research found that the D scale correlated so highly with the F scale that there seemed to be little difference in what they were measuring. In addition, the items of the D scale were also all formulated so that agreement always indicated high dogmatism so that it shared with the F scale the problem of being potentially contaminated by acquiescent responding. As with the F scale, attempts to balance the items of the D scale also resulted in the collapse of internal consistency of the scale. This suggested that the items of the D scale, like the F scale, could not be assessing a single personality or cognitive style dimension.

A third alternative conceptualization of the authoritarian personality was proposed by Wilson (1973), which he named Conservatism. Closely following Allport (1954), Wilson suggested that the basic personality characteristic involved in conservatism was a generalized susceptibility to experience threat or anxiety when confronted by uncertainty (p. 259). As a result, such personalities would adopt authoritarian or conservative social attitudes, which he developed a conservatism or C scale to measure. The items of the C scale consisted of attitudinal statements expressing dislike for and resistance to change, novelty, and diversity, and a preference for order, structure, tradition, and convention.

The C scale did improve on its predecessors by using items for which high Conservatism required both agreement and disagreement and so controlling acquiescent responding. Unfortunately, it also shared its predecessors' weakness, when balanced, of having extremely low internal consistencies with a typical mean correlation between its items being only about 0.05 (Altemeyer, 1981). This indicated that, like the F and D scales, also the C scale could not be measuring a unidimensional construct. Factor analytic studies of the C scale also did not reveal a meaningful factor structure that would enable the extraction of a unidimensional core of items. Finally, the items of the C scale were also similar in content to those of the F and D scales and it also correlated highly with the F and D scales suggesting little or no differentiation between what these scales were measuring.

In general, therefore, none of these alternatives to the original F scale managed to resolve the primary problem that their items, when balanced, did not covary sufficiently to indicate that they were measuring a single unitary construct. This meant that despite the appeal of the theories of an authoritarian (or dogmatic, or conservative) personality, none was able to produce a valid measure of such a personality dimension. As a result, by the end of the 1970s social scientists had largely lost interest in the idea that an authoritarian personality might be the underlying cause of people's ideological convictions. In the 1980s, however, an important new research revived the idea of an authoritarian personality.

Altemeyer's Authoritarian Personality

In 1981 an important book by Bob Altemeyer finally reported the successful development of a fully balanced and psychometrically sound Right-Wing Authoritarianism (RWA) scale to measure the authoritarian personality. The point of departure for Altemeyer's decade-long program of research had been his view that Adorno et al.'s (1950) nine traits and their attitudinal expressions in the F scale were far too broad to delineate a single unitary dimension. His research instead suggested that only three of the original nine traits and their corresponding attitudinal expressions were correlated together strongly enough to describe a unitary dimension. The three traits were 'conventionalism,' 'authoritarian submission,' and 'authoritarian aggression' and the items of the RWA scale were therefore limited only to attitudinal expressions of these three components. Altemeyer (1981) therefore defined RWA, which he saw as direct measure of the authoritarian personality syndrome, as consisting of the covariation of these three highly correlated traits (Altemeyer, 1981: pp. 147–148). A series of validation studies revealed that the RWA scale had excellent psychometric properties. Despite its items being balanced against acquiescence, they showed a high level of internal consistency and seemed to be assessing a single unitary dimension. Moreover, it substantially outperformed a number of earlier measures of the authoritarian personality in predicting presumed effects of RWA, such as holding right-wing political attitudes, generalized prejudice against out-groups and minorities, and support for punitive and unjust actions by established authorities against persons or groups regarded as deviant.

A series of subsequent studies by Altemeyer (1981, 1988, 1996) explored the psychological origins of RWA. Consistent with prior findings using the F scale, there was little support for Adorno et al.'s (1950) original psychoanalytic theory. Thus, correlations between parental punitiveness and strictness in child rearing and the RWA scores of their offspring were weak or not significant. Moreover, signs of repressed aggression in daydreams and fantasies were no more common among high than among low RWA scorers. Altemeyer's (1996) findings also suggested that RWA did not develop in early childhood but was largely formed through social learning and personal

experiences and crystallized during late adolescence. Moreover, despite RWA scale scores being generally stable over time, his research also showed that they could be substantially changed by experiences throughout the life cycle. Thus, RWA decreased substantially with liberal higher education, increased as a result of becoming a parent, and increased in response to threatening social crises. His research also showed that high scorers on the RWA scale seemed to have been socialized to view the world as a dangerous and threatening place, and that this motivated authoritarian behavior, such as aggression and punitiveness, toward persons targeted by the authorities.

A Second Authoritarian Personality?

Another important development in authoritarianism research came in the 1990s with the concept of Social Dominance Orientation (SDO) (Pratto et al., 1994; Sidanius and Pratto, 1999). SDO was conceptualized as a "general attitudinal orientation toward intergroup relations, reflecting whether one generally prefers such relations to be equal, versus hierarchical" (Pratto et al., 1994: p. 742), and measured by a highly reliable and unidimensional SDO scale with items such as 'Inferior groups should stay in their place' (agreement indicating high SDO) and 'No one group should dominate in society' (agreement indicating low SDO).

Although the item content of the SDO scale was therefore quite different from that of the RWA scale, and scores on the two scales were generally not correlated or only very weakly correlated, some striking similarities between the two measures soon became apparent. Both were strong predictors of right-wing political attitudes, as well as nationalism, militarism, and support for tough, undemocratic, authoritarian government. Both also strongly predicted generalized prejudice against outgroups and minorities. Finally, the social attitudes comprising SDO were, at least initially, also seen by Pratto et al. (1994) as direct expressions of a basic personality dimension. Altemeyer (1998) noted that the RWA and SDO scales seem to relate to different sets of the original nine 'trait' clusters listed by Adorno et al. (1950), and therefore concluded that these scales measure two different kinds of authoritarian personality dimensions (the 'submissive' and the 'dominant').

The idea that there are two 'authoritarian' dimensions did help to explain the checkered history of the authoritarian personality and the difficulties of the early theorists. In retrospect, it was apparent that Adorno et al.'s (1950) original conceptualization of the authoritarian personality and their F scale combined these two dimensions and syndromes, resulting in its lack of unidimensionality. Allport (1954), Rokeach (1960), and Wilson (1973) had attempted to simplify the conceptualization of this personality tending to focus on characteristics of the 'submissive' authoritarian, but they failed to narrow their measures correspondingly, which remained multidimensional. The success of Altemeyer's (1981) RWA scale thus seems largely because of him having stripped off those items tapping the factorially different 'authoritarian dominance' syndrome in his item development studies, which had now reemerged in the SDO scale.

Further research by Altemeyer (1998) and others (Duckitt, 2001; Duriez and Van Hiel, 2002; Van Hiel and Mervelde, 2002) confirmed that RWA and SDO, despite their common ideological outcomes, were two independent, individual, different dimensions correlating quite differently with a range of other variables. RWA was powerfully associated with religiosity and valuing order, structure, conformity, and tradition, seeing the social world as a dangerous place influenced by social threat, while SDO was not. SDO, on the other hand was strongly associated with valuing power, achievement, and hedonism, being male, and with a Social Darwinist view of the world as a ruthlessly competitive jungle in which the strong win and the weak lose, while RWA was not.

By the turn of the century, therefore, Altemeyer's (1998) conclusion that two quite different personality dimensions underlay people's ideological beliefs and a wide range of related social attitudes and behaviors had come to be widely shared by researchers. During the next decade, however, the assumption that these were personality dimensions came to be seriously questioned leading to the development of new theoretical models of the psychological bases of ideology.

The New Critique of the Idea of Authoritarian Personalities

A major criticism of the theory of an authoritarian personality, or personalities, which gathered force during the next decade, was that neither the RWA or SDO scale, nor indeed any of their predecessors, such as the F, D, and C scales, actually measured personality (Duckitt, 1989, 2001; Feldman, 2003; Van Hiel and Mervelde, 2002). The items of all these psychometric measures consisted entirely of statements of belief and attitude of a broadly ideological nature and did not describe behavioral dispositions or tendencies as the items of personality inventories typically do. Indeed, after their initial article presenting the SDO scale, Sidanius and Pratto (1999) have generally described it as a measure of enduring beliefs rather than of personality. The idea that the social attitude and belief items comprising the RWA and SDO scales measure personality was therefore merely an assumption that had never been empirically demonstrated. This meant that these scales were better construed as measuring exactly what their item content specified, that is, social and ideological attitudes or value dimensions.

There was also empirical support for the contention that the RWA and SDO scales were measures of attitude or value dimensions rather than personality. For example, Altemeyer's (1996) own research had shown that RWA did not seem to be established in childhood as one might expect for a personality trait, but only in late adolescence through a process of social learning. Moreover, although individuals' level of RWA once established seemed to remain reasonably stable during adulthood, it could be markedly altered by changes in their social situations or life experience, such as higher education, becoming a parent, or confronting threatening sociopolitical crises, which again seemed more consistent with it being an attitudinal construct rather than personality. In addition, studies investigating the structure of sociopolitical attitudes and sociocultural values had typically revealed two roughly orthogonal dimensions, with one corresponding closely to and correlating strongly with RWA, and the other to SDO

(Duckitt and Sibley, 2009: Table 1; see also; Duriez and Van Hiel, 2002; Duriez et al., 2005; Saucier, 2000). Again, therefore, these findings suggested that RWA and SDO were measuring social attitudes or values rather than personality.

Finally, research has shown that both RWA and SDO were powerfully influenced by social situational factors. Thus, social threats (such as social, economic, political crises, and instability) assessed at both the societal and the individual level significantly increased societal or individual levels of authoritarianism, whether measured by the F, C, or RWA scale or by independent ratings (e.g., Doty et al., 1991; Duckitt and Fisher, 2003; McCann, 1999; Sales, 1973). The role of threat as a possible primary explanation for RWA, had been, however, largely ignored by theorists, presumably because it did not fit well with the prevailing assumption that authoritarian attitudes were a direct expression of personality. In addition, research has shown that SDO was markedly influenced by membership of dominant social groups, and will shift accordingly when in-group power and status changes (Huang and Liu, 2005).

Beyond the Authoritarian Personality

This critique of the idea of an authoritarian personality (or personalities) has led to the emergence of new theories conceptualizing authoritarianism not as personality but as social attitude and value dimensions (Duckitt, 1989, 2001; Duriez and Van Hiel, 2002; Feldman, 2003; Kreindler, 2005). This reconceptualization has opened up issues and questions that had largely been ignored because of the personality assumption. First, an issue that had been completely neglected in the case of RWA (though less so for SDO), was that of identifying the central, core value or set of values underlying the seemingly diverse attitudinal content of the RWA scale's items that resulted in them cohering together to form a single unitary ideological dimension. The second has been the issue of what personal or social factors causally influence people's adoption of the ideological attitudes assessed by the RWA and SDO scales? And third, how do these social and ideological attitudes influence social outcomes such as generalized prejudice against out-groups and minorities?

An early alternative to the personality concept of authoritarianism was the group cohesion model of RWA (Duckitt, 1989). Although this model did not generate much research itself, its core ideas were adopted by more influential later models. The group cohesion model saw RWA as a social attitude dimension of a broadly ideological nature, and not as a personality dimension. It proposed that the three components of RWA identified by Altemeyer (1981) were not covarying personality traits, but attitudinal clusters, which covaried tightly together because all the three expressed the motivational goal or value of group cohesion, articulated in attitudes favoring the subordination of individual autonomy and self-expression to group cohesion and authority. Thus, Altemeyer's (1981) 'conventionalism' component was expressed in attitudes favoring the maintenance of the traditional norms of the group, his 'authoritarian submission' in attitudes favoring obedience and respect to group leaders and authorities, and his 'authoritarian aggression' in attitudes favoring punitiveness toward those who violated traditional group norms and conventions. This model suggested that the degree to which people would value group cohesion and therefore hold authoritarian attitudes would be jointly determined by the degree to which they identified with their social group and perceived threats to it. Out-group dislike or prejudice would therefore be caused by perceiving out-groups as threatening in-group cohesion or security in some way.

An interesting implication of this theory was that authoritarian attitudes could be held in respect of any social group. The items of the RWA scale (and of its predecessors) were formulated at the societal or national level so that the RWA scale measured authoritarian attitudes only in relation to the individual's society or nation. This group cohesion model was later elaborated by Stellmacher and Patzel (2005), who developed a General Authoritarianism scale with items that could be applied to any social group and so measure authoritarian attitudes in relation to any group (e.g., such as political parties).

A second theory influenced by the group cohesion model was proposed by Feldman (2003). He also viewed RWA, or at least its core authoritarian submission items, as an attitudinal expression of the value of group conformity or cohesion as opposed to individual autonomy. Feldman's theory did not attempt to explain what caused individuals to adopt the authoritarian values of group conformity or cohesion, but did suggest that once they held these values their perception of threats to cohesion and conformity in their groups would cause them to adopt and support authoritarian policies and actions (this included Altemeyer's 'authoritarian aggression' component) and direct prejudice at those seen as threatening in-group cohesion and conformity.

A third model influenced by the group cohesion Model was Kreindler's (2005) Dual Group Processes Model (DGPM), which also saw authoritarianism as a group phenomenon, and therefore potentially applicable to any social group. Like the group cohesion model the DGPM saw the primary causal determinant of RWA as identification with a group which was experiencing threats to its core norms, which caused hostility to those seen as responsible for these normative threats. The DGPM extended this group identification hypothesis to explain SDO as well, which it suggested was caused by identification with high status or dominant groups that resulted in high-group identifiers valuing inequality, hierarchy, and group dominance, and derogating members of lower status groups.

The most comprehensive and best researched theory deriving from the original group cohesion model has been the dual process model (DPM) of ideology and prejudice (Duckitt, 2001; Duckitt and Sibley, 2009). The DPM proposes that RWA and SDO are social attitudinal expressions of two different basic value or motivational goal dimensions that are made salient for individuals by their personalities and socialized worldview beliefs. Following the group cohesion approach, the DPM proposes that RWA is an expression of the motivational goals or values of collective security and cohesion, which is causally influenced by personality (the Big Five trait dimensions of low openness and high conscientiousness) and the belief acquired through socialization that the social world is a dangerous and threatening (as opposed to safe and secure) place. SDO is seen as an attitudinal expression of the motivational goal or value of power, dominance, and superiority over others, which is causally influenced by the Big Five personality

trait dimension of low agreeableness and the belief that the social world is a ruthlessly competitive jungle in which the strong win and weak lose (as opposed to a cooperative place where people share with and care for each other). Because people high in RWA value collective security and cohesion, they will direct prejudice and hostility toward persons and groups seen as threatening collective security and cohesion. Persons high in SDO, on the other hand, value power, dominance, and superiority over others and will therefore derogate and dislike out-groups low in power or status (in order to justify their relatively superiority) and out-groups competing with their own group over relative power and status.

Finally, a motivated cognition theory of ideology has been proposed by Jost and his colleagues (Jost et al., 2003), which has similarities to the DPM and group cohesion theories, but also important differences. This theory sees RWA (and related constructs, such as the F, C, or D scales) as expressing attitudinal resistance to change, and SDO as expressing attitudinal support for inequality, as two components of a single higher order political conservatism dimension. Conservatism, and therefore both RWA and SDO, express motives to manage and control threat and uncertainty, which arise from social situational factors likely to activate threat and uncertainty, and dispositional factors indexing personal needs to avoid uncertainty and threat. Jost et al.'s (2003) motivated cognition theory is therefore similar to the DPM and cohesion theories in seeing conservatism not in terms of personality but as a social attitudinal or ideological dimension that is an expression of basic motivational goals involving needs to manage threat and uncertainty and which is influenced by both personality and situational factors. It differs, however, from the DPM in seeing political conservatism as a single higher order dimension comprising both RWA and SDO, which are therefore seen as having the same motivational, personality, and situational bases. It also tends to differ from the cohesion influenced theories by seeing RWA as a more limited construct, involving only attitudes expressing resistance to change instead of a broader range of social attitudes favoring the subordination of individuals to group authority and cohesion.

These new models of authoritarianism therefore differ from the traditional authoritarian personality theories in seeing RWA and SDO as social attitude dimensions that express basic motivational goals or values, rather than as personality dimensions. While these new models see authoritarian attitudes as influenced by personality, they also strongly emphasize the causal influence of social factors as equally or indeed possibly even more important. And finally, these new models help to explain why authoritarian attitudes might cause prejudice, an issue that the traditional authoritarian personality approach largely glossed over. During the past decade, both the DPM and Jost's motivated cognition approach have generated a good deal of supportive research (for reviews, see Duckitt and Sibley, 2009; Jost, 2009).

Conclusions

The concept of an authoritarian personality to explain patterns of relatively stable individual differences in a broad range of social, political, and intergroup attitudes and reactions emerged early in the twentieth century. Since then it has inspired a great deal of research and controversy, which have lead to two important changes in conceptualization and measurement. One change was away from trying to measure the entire range of attitudes and beliefs originally seen as comprising the authoritarian syndrome on a single psychometric dimension. These early measures, such as the F, D, and C scales, invariably failed, and this led to the discovery that this broad social attitudinal domain comprised two distinct dimensions, which seem to comprehensively organize individuals' social, political, and intergroup attitudes and their many manifestations.

The second change has come more recently. This has involved challenging the conception of authoritarianism as personality, be it one dimension or two. New theories have emerged which see the two dimensions of authoritarianism, RWA and SDO, not as personality dimensions but rather as two distinct social attitudinal dimensions expressing two sets of motivationally based social values. The main focus of these newer theories has been to clarify the values that lie at the core of ideological attitude dimensions such as RWA and SDO, how situational, experiential, and personality factors might influence these dimensions, and how and why RWA and SDO in turn affect social and intergroup behavior.

Abstract

Authoritarianism refers to a construct originally created to understand individual differences associated with intolerance, prejudice, and support of fascist ideology. Almost since its inception, the construct has been widely criticized, with shortcomings being identified in theory and measurement. A consensus, dominant in the literature of the last 30 years, distinguished authoritarians' submission to authority, adherence to in-group norms, and aggression toward deviants. However, with new approaches challenging this consensus, recent research focused on the dynamic aspects of authoritarianism, and the contextual circumstances under which it is aroused, and the process by which it shapes social and political attitudes.

The concept of authoritarianism was first introduced by Adorno et al. (1950) with the goal of understanding personality differences associated with intolerance, prejudice, and support of fascist ideology. Yet, almost since its inception, the construct has been widely criticized, with shortcoming being identified in theory and measurement. Challenging the psychodynamic origins of the concept, Altemeyer (1981) reconceived authoritarianism as reflecting a willingness to submit to authority, to adhere to and enforce in-group conventions, and a tendency to aggress against those who challenge established authorities or in-group conventions. Whereas these themes continue to persist in contemporary research, the last decade or so has sparked lively research activity and a continuous refinement of the construct. Authoritarianism is one of the most heavily researched individual-difference variables in the social and behavioral sciences, with researchers across various disciplines, including psychology, sociology, and political science, exploring its origins, nature, and consequences.

Origins

Research on authoritarianism is inherently linked to the emergence of fascist regimes in Europe in the 1930s and the subsequent violent oppression and persecution of social, religious, ethnic, and sexual minorities. Rooted in the psychoanalytic tradition, European psychologists sought to answer as to how and why an otherwise cultured and civilized society like Germany would support ethnocentrism making the Holocaust possible (e.g., Fromm, 1941). Theodore Adorno, a German Marxist theorist, and Else Frenkel-Brunswick, a German-Austrian psychoanalyst, both emigrants from Europe, joined forces with Berkeley psychologist Neville Sanford and his doctoral student Daniel Levinson, who were already working on the origins of anti-Semitism in personality structure. The research culminated in the volume *The Authoritarian Personality* by Adorno et al. (1950). Relying on in-depth interviews and survey research, the book presented in almost 1000 pages an ambitious attempt to integrate personality theory and psychoanalytical theory. The central characteristic of Adorno et al. approach was to locate the origins of the authoritarian personality in early childhood experiences. Consistent with the psychodynamic thinking of the day, Adorno et al. argued that authoritarianism was the result of harsh and punitive child-rearing practices where the child could never be certain of parental affection. This resulted in a deep-seated psychological conflict in which the desire for acceptance combined with rage toward the parents. Repressed hostility was eventually transferred onto minority groups, while individuals' desire for acceptance made them susceptible to the appeal for dominant leaders. The authors further argued that authoritarians had a 'weak ego,' which led them to adhere to conventional norms and values and made them intolerant of ambiguity. Thus, authoritarian tendencies, including prejudice and the willingness to aggress against members of other groups, were primarily a reflection of individual psychological needs, rather than the nature of intergroup relations or a particular political structure.

Along with their theoretical account, Adorno et al. (1950) provided a survey measure of authoritarianism, labeled the 'California F-scale.' This F-scale was used in thousands of publications (e.g., Meloen, 1993), which documented its association with an impressive array of social and political attitudes and characteristics.

Early Criticism

Publication of *The Authoritarian Personality* was followed by an extensive debate on the merits of the work, with many of the themes of this debate persisting in authoritarianism research to the present day. One concern was that the construct of authoritarianism was ideologically, rather than scientifically motivated, as it focused exclusively on the political right, but ignored authoritarianism on the left (Eysenck, 1954; Shils, 1954). This critique was justified in that much research on authoritarianism was indeed sparked by the experiences of right-wing extremism in Germany and Austria, with two of the authors having fled Nazi tyranny by migrating to the United States.

Another concern was the fact that the F-scale only included items where a higher level of agreement indicated a higher level

of authoritarianism (Shils, 1954). Even when the original authors made various attempts to control for this type of bias (Adorno et al., 1950), there was the possibility that individuals with a greater tendency to acquiesce might have been falsely identified as authoritarian. Commentators pointed out that the item content was often ambiguous, with double-barreled questions making it hard to interpret the meaning of responses. And, although the F-scale claimed to measure one coherent construct, factor analyses routinely demonstrated that it was in fact multidimensional with factors being difficult to interpret. As Altemeyer (1981) noted, factors did not map onto components of authoritarianism as hypothesized by Adorno et al. (1950).

Altemeyer's Reconceptualization

Within 30 years of the publication of *The Authoritarian Personality*, empirical support for the psychodynamic origins of authoritarianism remained largely elusive. But the F-scale remained empirically useful, and there were various attempts to conceptualize the construct based on learning experiences and social class. The reconceptualization that was by far most successful was by Bob Altemeyer (1981, 1996). Based on a sweeping critique of existing research, Altemeyer proposed a new approach to authoritarianism based on social learning theory. This approach was widely adopted during the 1980s and 1990s, and set the stage for much of the contemporary discussion of authoritarianism construct.

Altemeyer viewed authoritarianism as a cluster of learned attitudes that individuals acquire through their upbringing, and their interactions with peers, institutions, media, and the society at large. In line with the origins of the concept, he focused exclusively on authoritarianism on the political right where he distinguished three components: first, a willingness to submit to authority; second, a tendency to adhere to and enforce in-group norms; and third, a willingness tendency to aggress against those who challenge established authorities or in-group norms. This tripartite structure guided the construction of his Right-Wing Authoritarianism (RWA) scale and was subsequently confirmed through empirical research, even when Altemeyer continued to view RWA as a single coherent construct. Altemeyer continually updated his RWA scale after submitting it to repeated empirical tests, which produced a variety of versions of the same scale. Other than Adorno et al. (1950) F-scale, the RWA scale avoids potential response biases by using reverse-coded items; its psychometric properties are sound with Cronbach's alpha reliabilities routinely approaching, if not exceeding 0.90. Moreover, the availability of short versions of the instrument allowed for the inclusion of RWA measures in a wide range of studies.

Altemeyer's RWA conception is arguably dominant in the literature, and the RWA scale, with its different versions, is the most widely used authoritarianism scale used to date. It is a reliable predictor of a broad range of social and political attitudes, including prejudice, intolerance, religious fundamentalism, and sexual inhibition (e.g., Altemeyer, 1998; Sibley et al., 2006). Still, Altemeyer's approach has met with criticism, which has sparked continuous refinement of the concept of authoritarianism and its empirical assessment (e.g., Duckitt, 2001; Stenner, 2005).

Measuring RWA

In spite of the solid psychometrics of the RWA scale, research has challenged the claim that it represents one coherent construct. Factor analytic studies documented two or three independent factors (e.g., Feldman, 2003; Funke, 2005; Van Hiel et al., 2007). This prompted Duckitt et al. (2010) to measure each of Altemeyer's (1981) three components using separate scales. The authors noted that the components reflect the distinct constructs of Authoritarianism (authoritarian aggression), Conservatism (authoritarian submission), and Traditionalism (conventionalism). The resulting ACT model allows for the testing of differential predictions pertaining to different components of the model.

Another line of criticism refers to a confound between the content of the RWA scale and the content of attitudes that the RWA scale is often used to predict. For instance, some RWA items ask respondents as to what to do about societal minority groups. It is hardly surprising if RWA is then found to correlate with hostile attitudes toward specific minority groups. More blatantly, a correlation between most versions of the RWA scale and attitudes toward gays and lesbians may not be very informative because the RWA scale does include items referencing homosexuality. In other words, the item content of the RWA scale makes it impossible to distinguish between an authoritarian disposition and the social consequences of this disposition, thus producing potentially trivial findings. Feldman and Stenner (1997) and Stenner (2005) proposed that this is the unavoidable consequence when authoritarianism is conceived as a cluster of attitudes. These authors define authoritarianism as a generalized motive aimed at maintaining and creating order and uniformity, and measure it in a manner that is distinct from any social or political preferences (see also Feldman, 2003). Prominently, Stenner (2005) assessed authoritarianism via individuals' preferences of child-rearing practices, with authoritarian tendencies being reflected in a preference for well-behaved and obedient children, rather than independent and curious children. Notably, items focusing on children and child-rearing had always been part of Altemeyer's (1981) RWA scale.

But even though scholars differ in how authoritarianism was conceptualized and measured, Van Hiel et al. (2007) documented a remarkable level of convergence of different scales.

Authoritarianism and Conservatism

Some scholars have treated authoritarianism measures as a *de facto* measure of conservatism (e.g., Jost et al., 2003a). Whereas measures of conservatism and authoritarianism are often substantially correlated, Wilson (1973) argued that authoritarianism is but one specific manifestation of conservatism, and only becomes indistinguishable in the presence of threat (see below). The link between authoritarianism and social conservatism is well-documented, but authoritarianism is less-strongly related to the acceptance of inequality, and similarly

weakly, if not negatively, related to economic conservatism and (e.g., Van Hiel et al., 2007). Jost et al.'s (2003a) recent definitions of conservatism as implying the maintenance of the status quo and acceptance of societal inequality allows for a clearer conceptual distinction between conservatism and authoritarianism, even when this definition is not universally accepted (e.g., Duckitt et al., 2010).

Stenner (2005) offers to date one of the clearest definitional separations (but see Duckitt et al., 2010). According to Stenner (2005), authoritarianism is a motive aimed at reducing differences across space, whereas conservatism is a motive aimed at minimizing differences over time. Whereas authoritarian is focused on reducing diversity and increasing uniformity within today's society, conservatism is focused on maintaining stability and resisting change. Defined in this manner, authoritarians may support policies aimed at social change if they expect that those policies will produce greater uniformity. Conversely, conservatives might be supportive of diversity, civil liberty and individual expression if those are viewed as traditions or an established institutional reality. According to Stenner (2005) conservatives only gravitate toward authoritarianism when public opinion is fragmented, and they view established institutions as dysfunctional. But whereas authoritarians can be expected to limit individual freedom, conservatives are likely to defend freedom and democracy within an established institutional context (see also Feldman and Stenner, 1997).

Authoritarianism on the Left

A recurring theme in the literature on authoritarianism is the notion that left-leaning researchers are oblivious, if not willfully ignorant, of authoritarian tendencies on the left side of the political spectrum. This concern emerged in part because Adorno et al. (1950) had painted right-wingers in a decidedly unfavorable light, with authoritarians, preoccupied with their own childhood conflicts, being ready to engage in blind obedience and mass murder as long as it satisfied their psychological needs. Arguably, Adorno et al. (1950) had defined norm conformity and in-group solidarity as grounded in pathology and irrationality, and ignored left-wing extremism (Eysenck, 1954; Shils, 1954; Rokeach, 1960). A similar sentiment was echoed by Durrheim (1997), who argued that attempts of researchers to associate certain ideological beliefs with irrationality can be interpreted as an attempt to devalue said beliefs. Indeed, some may charge that authoritarianism research was little more than a thinly veiled attempt to denigrate conservative viewpoints. Even if this may be a minority position, the debate surrounding Jost et al.'s (2003a) comprehensive view of cognitive style and political orientation included Greenberg and Jonas (2003) pointing out that the rigidity and dogmatism of extreme left-wingers remained essentially unexamined.

There had been efforts to document that extremists on the left and right were largely similar in terms of their tough-mindedness (Eysenck, 1954) and their rigidity (Rokeach, 1960). However, convincing evidence for a left-wing authoritarianism remained largely elusive during the first 30 years of research on authoritarianism (Stone, 1980). Yet, when the end of the Cold War enabled broader access to eastern European samples, scales that were originally conceived as assessing RWA were found to be related to support for Communism (e.g., McFarland et al., 1992). This underscores that individual differences in authoritarianism might be best understood as disposing individuals to support an established social system that is compatible with authoritarians' preference for order and uniformity.

Additional evidence for left-wing authoritarianism was found in Belgium, even when the factor structure was somewhat different from RWA (Van Hiel et al., 2006). However, at present it is still unclear to what extent this concept and its measurement generalize to other contexts.

RWA versus Social Dominance Orientation

Over the last 20 years research on authoritarianism has been cross-fertilized by the emergence of social dominance theory and the widespread use of the Social Dominance Orientation (SDO) scale, which measures individual differences in the acceptance or support of hierarchy and inequality between social groups (Pratto et al., 1994). Though originally suspected to be redundant with RWA, research quickly documented only a modest correlation between the two (e.g., Altemeyer, 1998). Much of current research treats RWA and SDO as complementary, with RWA referring to authoritarian submission and SDO referring to support for power-seeking leaders. This broader conception of authoritarianism as a two-sided phenomenon is apparent in Duckitt's (2001) dual-process model of ideology and prejudice, which relies equally on RWA and SDO as constituent variables. Although the present review focuses on authoritarianism more narrowly, note that much of contemporary research assesses RWA and SDO in tandem (e.g., Duriez et al., 2008). Results typically reveal RWA and SDO as independent and additive antecedents of intergroup attitudes (e.g., Sibley, et al., 2006).

Developmental Origins of Authoritarianism

Advances in research on human genetics have long suggested that dispositions toward certain sets of attitudes and ideologies might be predicted by one's genetic heritage. Such evidence is also available for authoritarianism, with twin studies indicating that up to 50% of the interindividual variability might be transmitted genetically (e.g., McCourt et al., 1999). Yet, this finding also suggests that a tremendous amount of individual variance occurs due to environmental variability, even when heritability estimates might have been biased downward due to assortative mating (Kandler et al., 2012; see below). Moreover, with genetic influences being not necessarily deterministic, it is critical to understand the environmental circumstances under which certain genes might be expressed.

Even when they differed categorically with regard to the nature of the processes involved, both Adorno et al. (1950) and Altemeyer (1981) located the origins of authoritarian tendencies in individuals' upbringing, specifically the interaction between parent and child. Consistent with this idea, a number of studies documented that authoritarianism seems to be running in families, with there being a substantial correlation between

levels of authoritarianism in parents and their children (e.g., Duriez et al., 2008). However, it is unclear whether the intergenerational transmission of authoritarianism occurred due to socialization experience or the genetic similarity between parents and offspring. Notably, Duriez et al. (2008) documented that parents high and low in authoritarianism systematically differed in the kinds of goals that they fostered in their children, and that parental goals mediated effect of parental authoritarianism on their adolescent children's authoritarianism. This finding demonstrates the importance of socialization practices for the intergenerational transmission of authoritarianism.

Authoritarianism and Information Processing

Early on, research on authoritarianism made strong predictions about the cognitive characteristics of authoritarians. Authoritarians were expected to be less tolerant of ambiguity, more rigid and cognitively inflexible. In part because the former are characteristics of high cognitive functioning, authoritarians were also predicted to be lower in intelligence than nonauthoritarians (Adorno et al., 1950). This *rigidity-of-the-right* perspective was soon challenged by Rokeach (1960) who claimed that extremists, regardless of whether they are authoritarians on the right or committed communists on the left, should be equal in their level of rigidity. This might be dubbed the *rigidity-of-the-extreme* perspective.

Both perspectives received at least some support. Modest support only emerged for the *rigidity-of-the-extreme* perspective, and often authoritarianism was not directly assessed (Jost et al., 2003b). However, there is ample support for the *rigidity-of-the-right* perspective. Consistent with early research, measures of authoritarianism are often found to be associated with self-report measures of cognitive rigidity, intolerance of ambiguity, need for structure and low attributional complexity (Altemeyer, 1998; Kemmelmeier, 2010b; see Jost et al., 2003a for a comprehensive review). Conversely, they are negatively related to need for cognition, a construct measuring an individual's tendency to engage in and enjoy thinking (e.g., Kemmelmeier, 2010a).

However, as noted by Van Hiel et al. (2010), the meaning of a correlation between a self-report measure of authoritarianism and a self-report measure of cognitive style is inherently problematic because the presence of a method-related artifact cannot be conclusively excluded. Moreover, researchers have suspected allegedly value-neutral measures to be ideologically biased (e.g., Durrheim, 1997; Van Hiel et al., 2010). Thus, there has been a call for the assessment of objective performance measures, which allow more reliable inferences about individuals' cognitive processing. In one such attempt, Durrheim (1998) was unable to find a consistent relationship between authoritarianism and attitudinal ambivalence, that is, individuals' tendency to hold both positive and negative feelings toward an attitude object. Though based on self-reports of attitudes, measures of attitudinal ambivalence can be objectively computed and served as measure of tolerance of ambiguity. In contrast, Kemmelmeier (2010a) demonstrated that authoritarians were more likely to trust their intuition and engage in heuristic processing when solving reasoning tasks, even when doing so produced normatively incorrect solutions. This finding is in line with the observation that measures of cognitive ability or intelligence are generally, though not consistently, negatively correlated with measure of authoritarianism and right-wing attitudes (see Van Hiel et al., 2010; McCourt et al., 1999 for reviews).

Authoritarianism and Personality

A recent meta-analysis of the relationship between the Big-5 personality dimensions and RWA revealed a substantial negative correlation with openness to experience (Sibley and Duckitt, 2008). Whereas there was no association with agreeableness, extraversion and neuroticism, RWA also showed a weak, positive association with conscientiousness. These findings are broadly consistent with the notion that authoritarians prefer order and uniformity. But while authoritarianism may be derived from individuals' (lack of) openness to experiences and conscientiousness, Sibley and Duckitt (2008) argue that authoritarianism should not be itself regarded as a basic personality variable – contrary to Adorno et al. (1950). Rather, as suggested by Duckitt (2001), it might function like a value orientation. Consistent with the idea that personality traits motivate value concerns, which are then expressed through attitudes and behavior, Sibley and Duckitt (2008) demonstrate that RWA mediates the relationship between openness to experience and prejudice.

Authoritarianism and Well-Being

The authors of *The Authoritarian Personality* clearly viewed authoritarianism as psychologically maladaptive. Wilson (1973) likened the authoritarian personality to "a kind of *pathological syndrome* like psychopathology or schizophrenia" with various authors often taking it for granted that authoritarians are psychologically conflicted, highly anxious, and of low self-esteem. Yet, evidence of maladaptive implications of authoritarianism is mixed with most studies failing to document a link with psychopathology (see Van Hiel and De Clercq, 2009; Duriez et al., 2012 for reviews). Van Hiel and De Clercq (2009) demonstrated that authoritarianism might even shield individuals from the psychologically maladaptive consequences of adverse life events. This result was not corroborated by Duriez et al. (2012) who found authoritarianism to be linked to an increase in depressive symptoms over time. This is consistent with Bonanno and Jost's (2006) observation that increased levels of depression and posttraumatic symptoms persisted longest among those high-exposure survivors of the 9/11 attacks who also reported higher levels of authoritarianism. However, neither trait anxiety (Onraet et al., 2013) nor self-esteem (Altemeyer, 1998) appear to be associated with authoritarianism.

Authoritarianism and Gender

Authoritarianism has ample implications for gender and gender relations (see Peterson and Zurbriggen, 2010 for a comprehensive review). Women higher in RWA are more likely to pursue traditional career and family goals than women low in RWA,

with nontraditional role combinations being experienced as stressful. Similarly, high RWA women were more attracted to men with traditionally masculine characteristics than low RWA woman. On the other hand, high RWA men rated their own femininity to be low compared to low RWA men even when there was no difference with regard to self-described masculinity. In both men and women, high RWA was related to sexual conservatism, rape myth acceptance (i.e., the tendency to blame a rape victim for being raped), the rejection of casual sex, as well as a rejection of gay men and lesbian women. Overall, high RWA individuals seem to be committed to traditional conceptions of masculinity and femininity, and a traditional understanding of gender roles, with high levels of agreement between men and women. Arguably, this sets the stage for assortative mating, whereby men and women with similar social attitudes and political leanings are disproportionately likely to have children together (Kandler et al., 2012).

Authoritarianism and Threat

Critics of *The Authoritarian Personality* have long charged that Adorno et al.'s (1950) focus on within-individual dynamics failed to take changing social and political circumstances into consideration. Others questioned Altemeyer's (1981) social learning explanation as such processes cannot easily accommodate fluctuations in authoritarianism over time. Indeed, recent research has pointed to the paramount role that external threat plays in authoritarianism (Feldman, 2003; Onraet et al., 2013; Stenner, 2005).

Focusing primarily on archival data (Doty et al., 1991; Feldman and Stenner, 1997), the presence of threat has been found to be associated with an increase in authoritarianism as measured via increases in punitiveness, prejudice, intolerance, and aggression. Though various causal accounts were suggested for this type of main effect, authors typically explained increases in authoritarianism as the result of in-group solidarity and protecting one's society's integrity (e.g., Altemeyer, 1996; Duckitt, 1989; see below).

More recent approaches have focused on the interactive effect of threats and preexisting dispositions, such that threat activates authoritarian tendencies among individuals who are thus disposed, but not necessarily among those who do not harbor such motives (Duckitt, 2001; Feldman and Stenner, 1997). Stenner (2005) described this two-variable interaction as "intolerance = authoritarianism × threat" and labeled it the *authoritarian dynamic*. McCann (2008) illustrates this dynamic in an archival study of death penalties and executions in different US states. In conservative US states, higher levels of threat were associated with more death penalties and executions, consistent with previous findings that threat increases authoritarian responses. However in liberal states, higher levels of threat were linked to fewer death penalties and executions, suggesting that the presence of external threat only intensified the response based on a nonauthoritarian disposition. This finding is difficult to reconcile with the main effects model described above. It is also somewhat at odds with the observation of a rightward shift in ideology observed among high-exposure survivors of the 9/11 attacks in New York observed (Bonanno and Jost, 2006). Witnessing a horrific act of terrorism induced liberals, centrists, and conservatives alike to shift their political views toward the right.

Aside from threat activating any latent authoritarian dispositions, a pervasive finding in the literature is that, regardless of levels of objective threat, authoritarians are more inclined to view the world as a dangerous place (Altemeyer, 1998; Duckitt, 2001). Theorists generally assume that this heightened perception of threat is responsible for authoritarians' increased willingness to engage in aggression against deviants (e.g., McFarland, 2005). A complex simulation game reported by Altemeyer (1996) compared how a group of high-RWA versus a group of low-RWA individuals would run the world for 40 years. The high-RWA simulation eventually ended in a nuclear holocaust and the death of the world's population. By contrast, the low-RWA simulation eventually resulted in a more or less stable world order in which pressing problems were by and large cooperatively addressed. Altemeyer (1996) attributed the failure of the high RWA group primarily to their distrust of others, which steered them toward aggressive action early on.

Authoritarianism as a Group Phenomenon

The question of the importance of threat for authoritarianism is embedded into the broader question as to the origins and purpose of authoritarianism as a social phenomenon. Adopting an evolutionary approach, there is evidence that differences in the prevalence of authoritarian forms of government as well as the prevalence of individual-level authoritarianism are related to the historical prevalence of pathogen prevalence and the stress that pathogens imposed on ancestral human societies (Murray et al., 2013). The explanation of this relationship focuses on the notion that in premodern societies, authoritarianism facilitated a collective response focused on isolating infected individuals. At a time when disease-causing processes were poorly understood and effective treatments were not available, disrupting pathways of infection by avoiding contact with pathogen carriers was the only means of protecting a collective. This may have fostered behavioral norms that focused on conformity because individuals with symptoms of disease were necessarily deviant; thus, rejecting deviant individuals meant avoiding contact with the carrier of a pathogen. Conversely, nonconformity might have either exposed individuals to pathogens or rendered them suspect in the eyes of fellow in-group members, who would then treat them as deviant. In this manner, fear of infection may have also promoted forms of governance that enforced order and uniformity. According to this account, authoritarianism is ultimately an evolutionary adaptation in response to environmental threat (Murray et al., 2013).

Even though this evolutionary account has not yet been widely embraced, it nevertheless conceives of authoritarianism as a response that is inherently embedded in a group process – an idea that has gained increasing prominence in research on authoritarianism. Duckitt (1989) first proposed that authoritarianism is best conceived as the normative expectation of individuals' conformity to and identification with the group for the purposed of enhancing group cohesion. The notion that authoritarianism is inherently a phenomenon

that is aimed at fostering in-group uniformity and cohesion, implying a rejection of deviants and nonconformists, is now a central element in theories of authoritarianism and prejudice (e.g., Duckitt, 2001; Feldman, 2003; Stenner, 2005). Although individuals vary in the extent to which they possess a disposition toward hostile responses toward deviants, such responses should be primarily expected in the presence of perceived threat to one's group, not necessarily in response to threats to one's well-being. Consistent with this idea, Onraet et al. (2013) show that only external threats (e.g., perceived threat to the integrity of one's society) were strongly and consistently related to authoritarian views, whereas the relationship for internal threats (e.g., anxiety, psychological distress) was weak and inconsistent.

Authoritarianism in International Perspective

Much of the research on authoritarianism originated in the United States and Canada, but research on the construct was never limited to North America. The popular RWA has been translated in various different languages or adapted to different culture contexts, and it yields results that are largely consistent across cultures, while also revealing cross-cultural differences (e.g., Duriez et al., 2005). Evidence of a possible link between cultural values stems from a study involving seven societies, in which RWA was found to be correlated with vertical collectivism, a value construct that measures individuals' respect for and willingness to submit to culturally sanctioned authority (Kemmelmeier et al., 2003). At the same time, RWA was not associated with horizontal individualism, a value orientation focused on individual self-determination and personal uniqueness. The only exceptions were postcommunist societies where the link between RWA and horizontal individualism was negative, presumably because totalitarian had rendered it salient that authoritarian tendencies were incompatible with the pursuit of personal freedom.

Conclusion

Since its inception, the concept of authoritarianism has demonstrated a remarkable degree of longevity. Yet, research on authoritarianism has been successful because it was never beholden to its theoretical beginnings, but continuously evolved. Rather than understanding authoritarianism exclusively as a personality variable, progress in theorizing over the last 10–15 years has clarified the nature of authoritarian dispositions and processes, and examined their activation and emergence within threatening social contexts. Of particular importance were new approaches, which allowed for a sharper definition of the authoritarianism concept and enabled its integration in more encompassing theoretical frameworks. And whereas much research has expanded our knowledge of the implications of authoritarianism, often yielding surprising results, contributions of behavioral genetics and developmental research have opened new pathways of understanding how authoritarian dispositions might be passed on across generations. Still, significant challenges remain, including a better understanding of the nature of threats, which arouse authoritarian responses, the variability of such responses over time and across situations, as well as the role of socialization practices and societal institutions in enhancing or mitigating authoritarianism. However, the last two decades have shown that authoritarianism is not only a reliable individual-level predictor of prejudice and intolerance, but that it enables substantial insights into the origin and dynamics of social attitudes.

Abstract

Authority is a concept denoting a relationship of unequal power, where those who have authority demand obedience from others who are expected to accept the legitimacy of those demands and comply with them. Authority is an elementary form of social life, found in all societies, and in all social institutions.

Theoretical Sources

Theories and Ideologies

For centuries philosophers have written about authority, but they have been less interested in analyzing authority objectively than in using the term ideologically to further their own intellectual agendas regarding justice, power, domination, and government. After all, as one very famous philosopher, Bertrand Russell, has said, "most philosophy has been a reaction against skepticism; it has arisen in ages when authority no longer sufficed to produce the socially necessary minimum of belief, so that nominally rational arguments had to be invented to secure the same result" (Russell, 1960: p. 86). With Russell's pronouncement in mind, this discussion will concentrate on value-neutral social science theories of authority, rather than surveying the vast philosophical literature on the subject.

German Theorists

Most ideas about authority have emanated from the work of Max Weber, who gave us the most basic and up to now most pervasive ideas about how power becomes authority through what he considered its three basic legitimations: traditional authority, rational-legal authority, and charisma. Although Weber is justly famous for his discussions of authority, one should acknowledge that his personal contact with historians, sociologists, and theological thinkers such as Rudolph Sohm, Adolf Harnack, Ernst Troeltsch, and Georg Simmel, all of whom were writing about these three forms of authority before, during, and after he did, played a huge part in Weber's thinking. Indeed, in his well-known work on church history, *Kirchenrecht*, Sohm introduced the term charismatic organization (Sohm, 1892: p. 26), which Weber directly adopted for his theory of charismatic authority. Adolf Harnack's monumental three-volume *Lehrbuch der Dogmengeschichte*, or *History of Dogma*, was published right after Sohm's book, between 1894 and 1898, and also had a major impact on Weber's thinking about authority in the early Christian church, which he then applied to modern societies. Ernst Troeltsch, a close personal friend, and professional colleague of Weber, wrote extensively about premodern and modern forms of institutional authority. Troeltsch's *Protestantism and Progress* (2013) and his *Social Teachings of the Christian Churches* (1912) discussed organizational and personal forms of authority in both church and state, and his work influenced the formation of Weber's famous tripartite theory of authority (Schneiderman, 2013).

Georg Simmel, a German sociologist even more influential than Weber in his day, also wrote about authority, and his excursus on 'super ordination and subordination' remains one of the most inventive ways of thinking about the relationship of authority to power. In this essay, Simmel introduced the concept of the 'prestige leader,' who seems to wield exactly what Weber would later call charismatic authority (Simmel, 1950: p. 185). Robert Michels, Weber's most successful student, published a book, *Political Parties*, which introduced a new term to describe authority, 'the iron law of oligarchy,' which says that the authority of an oligarchic elite in any democratic institution is inevitable. Michels reminds us of the Weberian endorsed idea of a value-free sociology regarding the study of authority: "leadership is a necessary phenomenon in every form of social life. Consequently it is not the task of science to inquire whether this phenomenon is good or evil, or predominantly one or the other" (Michels, 1915: p. 364).With the unification of Germany into a major modern state in the late nineteenth century, these social science thinkers brought a new analytic interest in power and authority, and this is clearly reflected in their work.

French Theorists

French sociology was also quick to become interested in the nationalistic forces boiling up in Europe, and in the new movements to consolidate power and to create the basis of legitimate authority in France and neighboring states. Gabriel Tarde was the first French sociologist to write extensively about authority and its relationship to power in his 1899 book, *Les Transformations du Pouvoir*, where he defined authority as the right to be obeyed. Tarde's well-known three-pronged theory of social order, first introduced in his *Laws of Imitation*, namely, repetition, opposition, and adaptation, are applied to power and authority in modern societies. Tarde sees the origins of political and social authority of the modern state in the history of the family as a social institution, an idea that was later underscored by the American sociologist, Robert Nisbet, in 'Kinship and Power in First Century Rome' (Nisbet, 1999). Another notable French sociologist, Célestin Bouglé, wrote about authority and social class in his famous treatise, *Essais Sur le Régime des Castes*, reiterating a line of thinking originating with Alexis de Tocqueville's famous analysis of the origins of the French Revolution, *The Old Regime and the Revolution*, and leading up to Louis Dumont's work on caste and authority in the 1960s. The most important French sociologist was, of

course, Emile Durkheim who also wrote about authority in his work on law and education. For Durkheim, social authority was not only about roles and statuses in the social order, but also about collective representations and symbols, which exacted obedience to authority through its moral interface with the society. These French sociologists played a part in more contemporary thinking about the cultural and symbolic nature of obedience to authority discussed above.

Italian Theorists

Interest in authority, power, and politics in Italy was set in motion by the three wars of Italian independence fought in 1848, 1859, and 1866 and was further fueled by the unification of the various Italian states as the Kingdom of Italy in 1861. Thus, in Italy, as in Germany, the modern bureaucratic state came into existence late in the nineteenth century and created an interest in power and authority among early social scientists. Among the most important Italian social scientists writing on authority were Gaetano Mosca, Vilfredo Pareto, and Guglielmo Ferrero. As Italy underwent its transformation from an array of tiny principalities, to a loose confederation of small states, and then to a centralized modern state, social scientists became interested in the process of how centralizing power became centralized authority.

Gaetano Mosca, an Italian political scientist whose *Elementi di scienza politica*, first published in 1895, and later in an English translation, *The Ruling Class*, set forth a theory of elites that added a new dimension to theories of authority. Mosca's basic assumption is that all societies are composed of small elite ruling classes that demand obedience from large unorganized majority groups. The pivotal question for Mosca is how the leaders who wield authority do so. As he says, in any form of political organization, authority is either transmitted from above, downward in the political or social scale (he calls this the autocratic principle), or from below, upward (the liberal principle). Mosca also discusses how leaders are chosen to wield authority, or at least from where in the social order they are chosen. The two types of leadership recruitment are aristocratic and democratic. Aristocratic recruitment consolidates power and authority in the hands of a relatively few families over multiple generations, while democratic recruitment emphasizes rejuvenation of elites by bringing up new talented individuals from the lower and middle classes.

Mosca's types of recruitment to authoritative elite positions anticipated Vilfredo Pareto's even more well-known 'circulation of the elite.' Pareto's most famous work, *Mind and Society* (*Trattato Di Sociologia Generale*), published in 1916, analyzed regime change, where authority is transferred from one elite to another because of revolutions from below. Perhaps thinking of the situation in Italy during the decades of the second half of the nineteenth century, Pareto was able to generate a theory of how social and political authority changes hands due to a constant pressure to change leaders.

Another Italian social scientist, Guglielmo Ferrero, wrote extensively about power and authority in his historical works about the Roman Republic and the Empire. He also visited America at the invitation of President Theodore Roosevelt, and wrote a book called *Ancient Rome and Modern America*, in 1914. In this book, Ferrero said of America that "Every authority is losing power." According to Ferrero, everywhere he turned he saw a nation that, judged by European standards, defied tradition and authority. "The people discuss the government and the laws, children take the first opportunity of escaping from the authority of their parents, the younger generation is convinced that it knows more than the older, and values the latter's experience at zero" (Ferrero, 1914: p. 204). These observations led Ferrero to distinguish between authority in what he called defiant democracies and authority in those societies that he called deference democracies. Deference democracies favored legitimate authority, according to Ferrero, while defiant ones bring power to the fore since they question legitimacy incessantly. These theories of how authority circulates throughout the social order later influenced the thinking of American sociologists from Talcott Parsons to E. Digby Baltzell.

British Theorists

Interest in authority among British social scientists is exemplified not only by James Bryce, but also by Walter Bagehot and Harold Laski. As Perry Anderson astutely observed, there really was no effective effort to build a British sociology until after World War II (WWII). Even absent a full-blown sociology, British social scientists showed a lively interest in authority. The English statesman, political scientist, and sociologist James Bryce's study of democracy in the *American Commonwealth* and later in *Modern Democracies* exposed the give and take between leaders and citizens in the modern state, and his essay, 'Obedience,' is a remarkable dissection of why an authority effectively commands obedience on the basis of indolence, deference, sympathy, fear, and reason (Bryce, 1901). Indolence is again emphasized as a reason for obedience in Bryce's 1909 Yale Lectures, *The Hindrances to Good Citizenship*. Bryce's contemporary Walter Bagehot also took up the study of deference and obedience to authority in his well-known *English Constitution*, and comes very close to what Weber later called traditional authority. In his discussion of tradition and authority, Bagehot says, "custom is the first check on tyranny; that fixed routine of social life at which modern innovations chafe, and by which modern improvement is impeded, is the primitive check on base power" (Bagehot, 1867: p. 26). In other words, tradition embedded in custom acts to legitimate power, and it becomes authority. In *Authority in the Modern State*, another English social scientist, Harold Laski, wrote that the basis for obedience to authority is consent. In this he added his voice to many social scientists linking authority to freedom in the contemporary state. If one freely consents to obey authority, its legitimacy becomes more pervasive than if one were forced to obey by dint of raw power.

This brief overview about who among the early European social scientists wrote about authority shows that social science responded to the sociopolitical events dominating the continent. It is interesting that American social science took very little notable interest in authority until the post-WWII period. This American neglect of a major social science concept is neither an accident nor a quirk. It gives us an opportunity to see that social theory is at least in part a mirror for understanding the social and historical conditions of the times and places in which they are produced.

American Theorists

During the second half of the nineteenth century, European nations underwent births and rebirths of nationalism, bureaucratization, and centralization, and while these forces were also at work in America they did not materialize as focal points because politics was subsumed by civil society and treated like any other associational influence. American social scientists generally saw politics as just another part of the associational life. Authority was viewed as just part of the fabric of association in America. Except for E.A. Ross' 1901 book, *Social Control*, hardly any of the great founding generation of American social scientists wrote about authority, and it was not until well after World War I that authority showed up on the American social science horizon. Beginning in the 1930s, Robert MacIver began writing about authority, as did Harold Lasswell, Talcott Parsons, Pitirim Sorokin, and Carl Friedrich, among others who were acquainted with the European literature and began applying it to America. It is notable that these social scientists imported and modified German, French, and Italian theories of authority rather than creating genuinely American theories.

Weberian Concepts

As noted, the most influential discussion of authority is found in the work of Max Weber, one of the founders of modern sociology. It is rare for any social science discussion of authority to omit Weber's analysis of power, authority, and legitimacy. Weber was interested in forms of power, *Herrschaftstypen*, or types of domination. The term *Herrschaft*, which means rule or domination, has come to be popularly translated as authority, and sometimes as legitimate power. Indeed, Weber's studies showed that all societies established and maintained authority on the basis of one or another type of legitimacy. Although Weber understood that authority rarely if ever existed in its pure form in any social organization, he categorized these types of authority as traditional, rational-legal, or charismatic.

Traditional Authority

Traditional authority, or what Weber called *die Autorität des ewig Gestrigen*, the authority of the eternal yesterday (Weber, 1948: p. 78), rests on legitimacy conferred by custom. He says that traditional legitimacy justifies the use of power by sanctifying the mores by appeals to 'ancient recognition,' and to accepted practices. Some of the examples Weber uses to illustrate traditional authority are hereditary rulers, religious priesthoods, parents, and elders in extended families. Later American sociologists, such as Edward Shils and Robert Nisbet, further explored the bases for traditional authority extending the term to explain the overarching authority of the royal family in Great Britain, and the traditional authority of fathers, *patres familias*, regarding citizenship, and life and death authority over their extended families, in ancient Roman society (Shils and Young, 1952; Nisbet, 1999). The sociological theory of traditional authority always takes tradition, custom, hereditary or ascribed status, and social norms burnished over long periods of time into account as essential to this form of legitimacy in relatively small and homogeneous communities, with simple divisions of labor.

Rational-Legal Authority

With the transition from medieval to modern societies and states in Europe, there emerged a powerful alternative to traditional authority: rational-legal authority, or power legitimated by a rational-legal and interdependent division of labor, characterized by economic and occupational specialization, and complex rational-legal systems, where highly specialized and differentiated bureaucracies and associations are commonplace. Weber called this rational justification for obedience to authority, "domination by virtue of legality, by virtue of the belief in the validity of legal statute and functional competence, based on rationally created rules" (Weber, 1948: p. 79). According to Weber, this is the authority "exercised by the modern servant of the state." Aside from bureaucracies, rational-legal authority is situated in constitutions and courts that interest these, achieved offices, such as those held by presidents, governors, and senators, rather than hereditary and ascribed offices held by monarchs and aristocrats. Structural complexity, complex organizations, and constant pressures to change are endemic to the world of rational-legal authority.

Weber's German sociological colleague, Ferdinand Tönnies, distinguished between two types of societies: communally, and rurally oriented *gemeinschaft-like*, rooted in families or neighborhoods, and ascribed statuses, on the one hand, and *gesellschaft-like*, exemplified by associational, rather than communal orientations, and achieved statuses, on the other. Sociologists have clearly understood that *gemeinschaft* societies are marked by traditional authority structures, and *gesellschaft* societies by rational-legal authority.

A younger colleague to both Weber and Tönnies, Herman Schmalenbach, wrote about a third form of social organization, *des bundes*, communions, that transcended the *gemeinschaft-gesellschaft* continuum and its relationship to traditional and rational-legal legitimations of authority. He showed clearly that these ephemeral forms of association are based on what Weber called charismatic authority, the third leg of his famous tripartite theory of authority.

Charisma

Charisma, according to Weber, "is the authority of the extraordinary and personal gift of grace." Weber used this ecclesiastical term to denote "the absolutely personal devotion and the personal confidence in revelation, heroism, or other qualities of individual leadership" (Weber, 1948: p. 79). This form of authority is useful for analyzing small, very cohesive inner circles of political, communal, and religious organizations. It is the authority of the revolutionary religious prophet, the political zealot, radically innovative entrepreneurs, and vanguard artists. Unlike traditional or bureaucratic authorities, these are individuals that demand obedience from their followers not on the basis of either ascribed or achieved status, but on their direct and personal connection to mystical powers. Although many social theorists have used the concept of charismatic authority, none have really transcended what Weber said about this form of legitimacy as "a certain quality of

an individual personality by virtue of which he is set apart from ordinary men and treated as endowed with supernatural, superhuman, or at least specifically exceptional powers or qualities. These are … regarded as of divine origin or as exemplary, and on the basis of them the individual concerned is treated as a leader" (Schneiderman, 2003). Religious leaders from Moses, Abraham, Jesus, or the prophets are seen as charismatic authorities, but so were more recent leaders on the edge of sanity and the good and evil divide, such as John Brown, Jim Jones, or David Koresh. Edward Shils extended the Weberian analysis of charismatic authority to events, places, and things, and Weber's colleague, Joseph Schumpeter, went even farther in applying charismatic authority theories to economic entrepreneurs.

While Herman Schmalenbach, Edward Shils, and Joseph Schumpeter extended Weber's theory of charismatic authority beyond Tönnies' *Gemeinschft und Gesellschaft* continuum, a later sociologist, Robert Bierstedt, raised the question as to whether or not charisma is actually a type of authority at all. Arguing that "a leader can only request, and authority can require," Bierstedt made the case that charisma is merely a type of leadership, not a type of authority. By setting Weber's traditional and rational-legal legitimations of authority along a continuum of organizational statuses terms, Bierstedt demonstrated that authority exists because statuses that carry authority exist. But because charismatic legitimacy inheres in the person, rather than in roles and statuses, "charismatic authority is not authority at all, but leadership." While this interesting line of reasoning runs counter to Weber's theory of authority, and also to Edward Shils' extension of that theory beyond leadership to events and things, it also offers a possible obstacle to an ever expanding list of studies of charisma. In the end, Bierstedt's argument that the entire collective symbolism of the society stands behind the traditional as well as the rational-legal forms of authority, offering no alternatives to obedience, seems in keeping not only with Weber's theory, but also with the French sociologist Emile Durkheim's theory of collective representations. If charismatic leaders cannot bring collective sanctions to bear on disobedience, do they really have authority, as Weber understood that term? This question is still worth pondering, 50 years after Bierstedt first asked it.

Obedience and Authority

One important question raised by Bierstedt's discussion of the relationship between authority and leadership is why authority is obeyed. Whether it is the authority conferred by status in the society, or by followers in smaller bundlike groups, authority always demands obedience, and its success or failure depends upon followers obeying authoritative demands, so why is authority obeyed?

Legitimacy

Before trying to answer the question of obedience, a baseline assumption is usually made, namely, when authoritative demands are considered legitimate by those who thereby willingly obey them, one has authority. When the demands are obeyed mostly out of fear of force being used, one has raw power. Power is the ability to make people do what they do not want to do, but authority is the ability to make them want to do what they start off not wanting to do. This assumption is problematic because it valorizes one important part of Weber's theory of power at the expense of an equally important but contradictory element of it. The problem is centered on Weber's often ambivalent use of terms, such as *Herrschaft*, or domination, *Autorität*, or authority, and *Macht*, or power. Thus, in Weber's most comprehensive chapter on authority in his magnum opus, *Wirtschaft und Gesellschaft*, or Economy and Society (Weber, 1922, 1978), Weber says that "Herrschaft ist ein sonderfall von macht" (domination is a special case of power), and a few paragraphs later he discusses "domination by virtue of a constellation of interests" (die Herrschaft kraft Interessenkonstellation), as opposed to "domination by virtue of authority" (die Herrschaft kraft Autorität).

These ambiguities in Weber's language of domination and authority have been noted and discussed by a number of social theorists including Steven Lukes, Guenther Roth, and Wolfgang Mommsen. This inexactness of terminology is yet to be resolved, and until it is there is a certain cloudiness that hangs over the social science theories of authority resting on Weberian foundations. Weber himself seems to have understood that legitimate domination, or authority, as one has come to understand the term, is different than power insofar as it is accepted by those over whom obedience is demanded. It is this acceptance to which one must turn to understand obedience to authority.

This Weberian perspective – problematic as it may be – has been emphasized by Hannah Arendt, in a famous article, 'What Was Authority?' in which she also demonstrates that there is nothing to be gained by discussing some vague 'authority in general' (Arendt, 1968). As she notes, authority is always alloyed to the dialectic of obedience and disobedience in a particular and specific social structure, and it makes no sense to discuss authority in a free-floating and overly general way. For Arendt, as for Weber in his somewhat convoluted but comprehensive treatment of domination, authority must be understood "in contradistinction to both coercion by force and persuasion through arguments" (Arendt, 1968: p. 93). It is in this theoretical context that one must try to understand why one obeys authority.

Power

The ability of authority to transform resistance to obedience into acceptance of obedience is usually attributed to what Weber called legitimation or justification of power. This transformation is what the author calls a social and cultural 'transduction.' In physics, a transducer is a device that transforms one form of energy into another, as when an electromagnet transforms electrical energy into magnetic energy, or an incandescent bulb transforms electrical energy into light. Weber's forms of legitimacy are sociocultural devices that transform power into traditional authority, or rational-legal authority, or charismatic authority.

What Weber lacked was an understanding about how these transducing justifications tuned power into authority, or, put differently, how a reluctant obedience to power is turned into a willing obedience to authority. Weber was well versed in the

work of James Bryce, and was definitely influenced by him. As noted earlier, Bryce's now much neglected essay, 'Obedience,' had a demonstrable effect on Weber's theory of authority. In 'Obedience,' Bryce was one of the first social scientists to use the term 'legitimate authority' as an analytical tool, and he narrowed down the transformational and transducive qualities that turn power into authority to indolence, deference, sympathy, fear, and reason, all of which would later become important to Weber's understanding of legitimacy.

So why do people obey authority? Traditional values, religious values, rational values, and the like actually become part of who one is, part of his or her identities, and if they justify obedience to authority, reluctantly obeyed power becomes transformed into happily obeyed authority. To get to deeper and more modern answers to the question about sociocultural transduction of power into authority, one must turn to later theorists.

Culture

Philip Rieff, a sociologist, understood cultures to be engines of moral demand, or what he called moral demand systems. Rieff was not the only theorist to see culture as a system of moral demands. In this he was joined by the anthropologist Clifford Geertz who saw culture as a set of symbolic control mechanisms that govern behavior. Both Rieff's and Geertz's theories of culture benefit from Sigmund Freud's psychoanalytical idea that symbols become introjected into the self, and made part of an individual's sense of identity.

These cultural theories were anticipated decades ago by social scientists influenced by pragmatist philosophy, such as George Herbert Mead, whose ideas about 'significant symbols,' lays the groundwork for understanding the transducive quality of cultural values. To this list of theorists one should add the philosopher Susanne Langer, whose *Philosophy in a New Key* has chapters on 'life symbols,' as the root of myth and of sacrament that provide key insights into how cultural symbols transform reluctant obedience to power into willing obedience to authority. As she says, "the human brain is constantly carrying on a process of symbolic transformation of the experiential data that comes to it that causes it to become a veritable fountain of spontaneous ideas" (Langer, 1942: p. 34). It is the seeming spontaneity and freedom of our ideas about the need to obey authority that gives it legitimacy.

A very different point of view about the reasons people obey authority was expressed by the social psychologist, Stanley Milgram, whose experiments about obedience were both brilliant and controversial. Milgram found that a disturbingly high rate of experimental subjects were willing to obey an authority figure wearing a lab coat, and professing to be in charge of a learning experiment. The subjects were instructed to give what they believed were electrical shocks in increasing intensities to a 'learner' whenever he got an answer wrong. After finding that a majority of subjects obeyed the authority figure, often in spite of professing to have moral qualms about inflicting pain on the 'learner,' Milgram tried to explain their obedience, first in part because of the cultural context of their upbringings, and then because of the institutional setting of the experiments. But, what is really interesting about Milgram's explanations, in terms of obedience to authority, is that the subjects responded to the perceived legitimacy of the experimentor. Very much in line with Weber's theory, and that of the culture theorists such as Rieff and Geertz, Milgram says that the first and foremost reason for obedience is "the perception of a legitimate authority" (Milgram, 1974: p. 138). This perception of legitimacy is a direct result of "the internalization of the social order – that is internalizing the set of axioms by which social life is conducted." Thus, from Bryce to Rieff, Geertz, and Milgram, one sees that one must turn to cultural symbolics of obedience to understand the transducive qualities in the Weberian justifications of authority.

The most basic paradigm for conceptualizing authority was the one set into motion by Max Weber, and he and others addressed how obedience to authority comes to replace obedience to power. The intellectual landscape of authority reveals when, where, and how authority was conceived as a social science concept.

While Western philosophers from Plato and Aristotle through Hobbes, Locke, Rousseau, Machiavelli, Kant, Hegel, Kierkegaard, and Nietzsche, among others, have thought about power and authority, their discussions generally pivot on either justifying or condemning hierarchical civic or political relations. Social science theories of authority, on the other hand, tend to ask and answer the problem-solving questions what, why, when, how, where, and who. In other words, social science theorists of authority, such as Weber and the other social scientists discussed above, are less interested in justifying or condemning authority, than in understanding it.

Abstract

Autism spectrum disorders are a family of conditions characterized by early emerging disruptions in social communication and restricted/repetitive behaviors. We will review recent research and current understanding on the evolution of the concept of autism, its clinical characteristics, its causes, as well as issues in clinical management, policy, and intervention. Given the relevance of autism for a scientific and cultural understanding of normative and atypical development of social behavior, research in autism has the potential to crucially inform knowledge in medical, biological, social, and behavioral sciences.

Evolution of the Concept of Autism (from Kanner to the DSM 5)

Autism is the diagnostic concept originally formulated by Leo Kanner (1943) to define a clinical syndrome characterized by early emerging social communication abnormalities and behavioral rigidity. Kanner's concept has proven influential and enduring, and interest in the nature and implications of this condition has grown exponentially over time. In the past decade, autism and related conditions have attracted increasing attention from a variety of different disciplines, including molecular biology, neuroscience, cognitive science, developmental psychology, pedagogy, psychiatry, philosophy of mind, linguistics, artificial intelligence, and anthropology.

Kanner's original description of 11 children affected by 'autistic disturbances of affective contact' emphasized a reduced or completely lacking interest in other people and a striking 'insistence on sameness' as the hallmarks of this condition. The validity of autism as a specific diagnostic concept has been supported in the following decades by various lines of research. In particular, studies documenting the early emergence of social disturbances, the presence of deficits affecting both language and nonverbal communication, and the discrepancy between social and nonsocial abilities in affected children pointed to a distinction between autism and other diagnostic concepts such as schizophrenia, language disorders, and intellectual disability (ID). Over the decades following Kanner's original report, the different definitions used to classify and diagnose autism have continued to be based on these two notions: impairments in social reciprocity and communication and insistence on sameness/resistance to change. The robustness of these diagnostic indicators is reflected in a report of the National Institutes of Health autism working group, written five decades after Kanner's description, which states that "the clinical diagnosis of autism is one of the most reliable diagnoses in psychiatric or developmental research" (Bristol et al., 1996). Despite the continuity between Kanner's original description and current definitions, the concept of autism has evolved over time as a consequence of cultural changes and research advances.

The most recent edition of the *Diagnostic and Statistical Manual of Mental Disorders (DSM-5)*, published by the American Psychiatric Association (2013), defines autism as a 'spectrum disorder,' rather than a single entity, with diagnostic criteria grouped in two categories: 'social communication deficits' and 'fixated interests and repetitive behaviors.' The notion of 'autistic spectrum' reflects the homogeneity in the core impairments, as well as the continuum of variability in the clinical presentation of these deficits. The current definition of autism as a spectrum represents a significant departure from previous approaches, which conceptualized autism and related conditions as a discrete number of mutually exclusive diagnostic categories. The International Classification of Diseases (ICD 10), published by the World Health Organization, is likely to incorporate these changes in the next edition. The concept of 'Asperger's disorder,' previously in use to define a 'subtype of autism' (DSM-IV), has become part of the mainstream vocabulary and is still culturally associated to autism, but is no longer relevant to diagnostic purposes. The terms autism and autism spectrum disorder (ASD) are now considered interchangeable.

Epidemiology

While the first studies in the 1960s indicated a prevalence of 4–5 in 10 000 for autistic disorder (as conceptualized in DSM-IV-TR), a recent review of epidemiological surveys conducted worldwide found a median prevalence of 19 in 10 000 for autistic disorder, which becomes 62 in 10 000 considering related conditions (Elsabbagh et al., 2012) with close correspondence in the estimates derived from North American and Northern European studies. Although the progressive rise in the prevalence in the last decades is irrefutable, the changes in the diagnostic criteria and the different methods used for case ascertainment influence the interpretation of the studies and do not allow to conclude that there is a correspondent increase in the incidence (or number of new cases per year) of the disorder. The factors presumably responsible for the increased prevalence include the progressive broadening of the diagnostic criteria (shown, for example, by a reexamination of the clinical records of a survey conducted in the 1980s using the case definition of DSM-IV-TR, Miller et al., 2013), the improved efficacy in the diagnostic procedures, and the increased awareness in health professionals as well as the changes in policies for access to services. In the United States, there is

evidence of ethnic and racial disparities in the identification of ASD (Mandell et al., 2009). The sex ratio (male:female) is 4.3:1, but there is suggestion that females are more likely to remain undiagnosed (Giarelli et al., 2010). Research on gender differences in the clinical phenotypes has mixed evidence, partly due to the fact that few female participants have been involved in research studies.

Clinical Features

Despite its biological roots, research has not identified yet a biological marker distinguishing ASD from other conditions. As a consequence, ASD can be diagnosed solely on the basis of behavioral manifestations. Moreover, autism is a developmental disorder; therefore, the presentations of symptoms are affected by and affect the developmental level of the individual (verbal ability and mental age), and the chronological age of the subjects influences the way in which these symptoms manifest themselves.

Social Communication and Social Interaction

Impairments in social communication and social interaction are a defining feature of autism (Carter et al., 2005); nonetheless, the presentation of symptoms in this area varies considerably across the life span. In infancy and early childhood, eye contact is often poor and the direct gaze may not indicate social contact with the carer. The ability to follow an adult's gaze or pointing is impaired and, while the awareness of other environmental sounds is intact, the response to human voices (for example, when the child's name is called) is delayed or lacking. Behaviors aimed at directing or maintaining the carer's attention to what the child is interested in – such as vocalizing, pointing to request or express interest, bringing objects to show them – occur with lower than expected frequency or are totally absent. When present, nonverbal communication (eye contact, gestures, facial expressions, body language) is poorly integrated with verbal or vocal communication. Social smiling may be lacking or occur only in response to prompts, and the behavioral cues that indicate the toddler's desire to show his/her enjoyment to the adult during joint activities may be very limited or absent. Turn-taking in the communicative exchanges with the carer in early infancy and the typical back-and-forth conversation after the emergence of language are impaired. Social play is very limited with failure to initiate or respond to social routines with an adult (such as peekaboo, patty-cake). Pretend and imaginative play, when present, may lack spontaneity or flexibility and are not shared with adults or peers. Relationships with peers may range from fewer attempts to approach other children to no interest at all and limited response or avoidance of their approaches. Response to others' emotions may be very limited or occur only in the presence of exaggerated expressions (e.g., adult pretending to cry). Delay or lack of development of spoken language may occur but is not a discriminating feature; however, it is highly indicative of ASD if not accompanied by attempts to compensate through the use of gestures. Abnormal speech patterns, odd words or phrases, echolalia, and unusual tone or pitch in vocalizations or words are other distinctive characteristics of early language in ASD and may persist throughout the life span. The use of communicative speech increases from childhood to adolescence and adulthood, but many aspects of communication, particularly the social components (such as pragmatics or prosody), are likely to remain impaired. Deficits in developing, maintaining, and understanding relationships (such as friendship) become more apparent in middle childhood, as the social demands increase. In adolescence and adulthood, for example, social interactions may increase in frequency but retain a qualitative impairment (stilted, exaggerated, or 'socially awkward' behavior).

Restricted, Repetitive Patterns of Behavior, Interests, or Activities

Repetitive and restricted behaviors (RRBs) are a heterogeneous group of symptoms that can emerge in infancy and persist throughout the life span; however, their manifestation may change with age. These behaviors are not a distinctive feature of ASD as similar phenomena are often observed in IDs, psychiatric disorders, neurological conditions and other clinical conditions with sensory deficits as well as in typically developing toddlers; however, ASD is usually characterized by a pattern of co-occurring behaviors. These symptoms include behaviors characterized by stereotyped or repetitive movements (such as motor stereotypies, repetitive use of objects) or repetitive use of speech (echolalia, idiosyncratic phrases) and restricted, fixated interests unusual in their intensity or focus (such as strong attachments to unusual objects, circumscribed or perseverative interests). The insistence on the sameness (such as the need to eat the same food everyday) and adherence to routines or rituals is another characteristic of ASD, often associated to high distress for the affected individual and impairment in everyday functioning. Seeking of specific sensations and unusual sensory interests (such as peering or smelling of objects) have been included in the DSM-5, together with hyper- or hyporeactivity to sensory inputs as important clinical descriptors of ASD. Within the autistic population, there is huge variability in the prevalence and severity of each of these types of behaviors. Behaviors like repetitive use of objects (spinning the wheels of a toy car) or motor stereotypies such as finger flicking or hand flapping are more likely to occur in children with ASD and ID than in children with ASD only, whereas circumscribed interests are more prevalent in higher-functioning individuals (Bishop et al., 2006). There is growing evidence that all kinds of RRBs decrease in frequency and severity with age, independently of co-occurring ID, with the exception of stereotyped movements that tend to be more persistent in individuals with ID (Esbensen et al., 2009).

Co-occurring Conditions

Once thought to be occurring in most cases of ASD, ID is now ascertained in approximately 50% of children diagnosed with ASD (CDC, 2012). In subjects with ASD, comorbidity with several psychiatric conditions (including anxiety, depression, hyperactivity and attention difficulties, oppositional defiant disorder, tics, and epilepsy) is increased compared to rates in the general population (Simonoff et al., 2013). The presence of mental health problems needs to be carefully assessed to

ensure appropriate support; however, the nature of the association between psychiatric conditions and ASD is still unknown.

Causes of Autism

There is incontrovertible evidence that genetic factors are the predominant cause of ASDs. Twin studies and family studies have documented that siblings of children with ASD have a 20- to 50-fold increased risk of having ASD compared to the general population, and the concordance rate in identical twins (who have 100% of genes in common) is up to 90% (Rutter, 2000). There is also evidence for a remarkable genetic heterogeneity in the etiology of ASD. A number of potential risk genes have been identified; however, none of them accounts for more than 1% ASD cases, and the combination of known genetic risk factors accounts for approximately 10% of ASD (Geschwind, 2006); in the remaining 90% of the cases, ASD etiology is unknown. It is currently estimated that many hundreds of genes might contribute to the risk of developing ASD. While genetic findings indicate that ASD is one of the most heritable neuropsychiatric disorders, the lack of complete concordance in identical twins indicates that nongenetic factors contribute to ASD as well. Several environmental factors have been found to be associated with increased risk of developing ASD, including prenatal exposure to rubella, thalidomide (a chemical compound that used to be prescribed to treat nausea and vomiting), and valproic acid. Recent research pointed to a possible association between ASD and exposure to chemicals in the environment (e.g., pesticides and air pollutants), but evidence is still inconclusive (Hertz-Picciotto et al., 2010). Advanced paternal age is also associated with an increased risk of ASD. Current evidence does not support the popular notion of a link between vaccines and risk for autism or the historical notion that poor parenting can determine autism. While it is clear that autism and related conditions result from a complex interplay of multiple genetic and environmental factors, the exact mechanisms that underlie both the homogeneity and the heterogeneity observed in ASD are largely unknown.

Several theoretical models of the neurobehavioral basis of ASD have been proposed. One line of research focuses on the possibility that a single neurocognitive process might explain the phenotypic presentation of autism. The many cognitive/neurocognitive explanations of ASD proposed within this framework share the view that different pathological pathways can ultimately result in one specific primary abnormality at the neurocognitive level, which, in turn, can determine the constellation of features (including strengths and weaknesses) that are observed in ASD. The primary deficits that have been hypothesized to underlie autistic features include difficulties in the ability to attribute mental states to others (i.e., theory of mind), a weak central coherence (i.e., a detail-focused processing style, whereby information is processed in terms of constituent parts, rather than global meanings), a deficit in executive functioning (i.e., difficulties in the flexible organization of behavior), and a deficit in affective connectedness/intersubjectivity (see Frith, 1996). More recently, the 'broken mirrors theory' (Ramachandran and Oberman, 2006) pointed to a primary deficit in the 'embodied' social understanding processes implemented by the mirror neuron system (a neural network that activates in response to both self-generated and observed actions and emotions). While each of these theories has some explanatory power and has generated important research, none of the proposed 'primary mechanisms' provides a satisfactory account for all the features observed in autism.

The current debate is focused on identifying the processes underlying specific features, such as social difficulties, rather than attempting to find a single explanation for all ASD symptoms. The complex information processing model (Minshew and Goldstein, 1998) posits that difficulties in handling information that is complex in nature affects the ability to process social stimuli (as they tend to be inherently more complex than nonsocial information). The social deficit models propose a specific difficulty in processing social versus nonsocial information, regardless of complexity level. Recent developmental models of social impairment suggest that a biologically based decrease in the salience or in the reward value attributed to social stimuli during early developmental stages virtually 'isolate' children with ASD from the social world, with downstream effects on social cognitive development (Chevallier et al., 2012).

Onset and Developmental Course

Historically, the onset of autism has been reported as occurring in one of two patterns. The 'early onset pattern' involves the early emergence of abnormalities affecting development from birth. In the 'regressive autism' pattern, on the contrary, children appear to be developing normally during early childhood, but then undergo a regression and lose previously acquired communicative and social skills. Recent research, however, has questioned the notion of a sharp distinction of 'early onset' versus 'regressive' autism (Ozonoff et al., 2008). In particular, a number of studies based on the prospective investigation of high risk samples indicate that at birth or shortly after birth children with autism are undistinguishable from those without autism (Yirmiya and Ozonoff, 2007). Abnormalities appear to emerge over the first 18 months of life, involving both a decline/regression in certain areas (e.g., social attention) and a failure to progress in other areas (e.g., language). Such delays and diminishments in typical behaviors occur at different points in development in different children, indicating a continuum, rather than a dichotomy, in the age of onset in autism.

Autistic symptoms are relatively stable, with most individuals who meet ASD diagnostic criteria in childhood continuing to meet criteria across the life span (for example, Howlin and Moss, 2012). However, the expression and the severity of the impairments seen in ASD can change over time. Studies on individual developmental trajectories point to a remarkable heterogeneity across functioning domains, which tend to increase with age. For example, a large cohort study (Anderson et al., 2007) documented that a subgroup of children with ASD made significant gains in communication, ultimately reaching 'normative' language level at 9 years of age, while another subgroup made little progress. Similar heterogeneity in developmental trajectories has been documented in the social domain, as well as in cognitive and adaptive functioning. There are also well-documented reports of children who have largely

or completely lost their symptoms of autism (Fein et al., 2013). Despite this remarkable variability in individual trajectories and outcomes, existing evidence suggests that the majority of adults in the autism spectrum, including those who had an average cognitive functioning at the age of diagnosis, experience very limited social inclusion, do not have a paid employment, and are not able to live independently.

The processes underlying these heterogeneous patterns of onset and developmental course of autistic symptoms are largely unknown. Existing research indicates that a complex interplay of biological and environmental risk and protective factors, rather than a single mechanism, might be at the origin of the diverse expression of clinical features in the ASD population.

Clinical Management

Diagnosis and Assessment

In most countries, diagnosis is based on the criteria specified in the DSM-5 or the ICD 10. Ascertainment of behavioral manifestations of ASD is achieved through a combination of direct observation and parent questionnaires focused on the child's developmental history. A number of standardized protocols such as the Autism Diagnostic Observation Schedule (Lord et al., 2006, 2012) and the Autism Diagnostic Interview-Revised (Le Couteur et al., 2003) have been developed to facilitate differential diagnosis between ASD and conditions that share superficial features (e.g., ID, attention deficit hyperactivity disorder, reactive attachment disorder, specific language impairments, and other communication disorders). To lower the age of diagnosis (often exceeding 4 years of age, CDC) and consequently facilitate early access to intervention programs and services, screening and developmental surveillance are recommended (Johnson and Myers, 2007). Further research is needed to establish whether a broad developmental screener is preferable to ASD-specific tools. Beyond the 'core' symptoms, ASD affects the individual's functioning such as cognitive, language, and adaptive skills in a variety of domains. A comprehensive developmental assessment delivered by a multidisciplinary team that considers these as well as other aspects (e.g., the presence of challenging behaviors) is therefore essential to identify strengths and weaknesses of each individual in order to build and monitor intervention programs tailored on the child's specific needs and resources. As the presence of co-occurring ID can affect the symptomatology, it is important to take into account the developmental level of the child in the clinical assessment in order to tease out the differential contribution of ASD and ID to the presentation of symptoms. Given the variability in the behavior of individuals with ASD across settings (e.g., the same child might show few social initiations in an unfamiliar context, but initiate often in a familiar context), the involvement of parents in the assessment as a source of information is critical.

Treatment

Currently there is no cure for autism, and the issue of treatment for such a heterogeneous condition whose etiology is uncertain is a highly debated topic. While the unethical and unsupported treatment approaches that were used until the 1970s (such as the institutionalization of children to remove them from their parents and the use of electric shocks to suppress abnormal behaviors) are no longer included in the current treatment guidelines, there is no general consensus on this subject. A number of self-advocacy organizations question the need of treating autism, on the basis of the notion that autism is a way of being in the world, or a culture, that should be supported and appreciated rather than treated. Others, while advocating for a shift from a medical model (which aims at eradicating/curing deviations from normality) to a social model (which focuses on environmental and social barriers to civil rights and inclusion), acknowledge the importance of interventions aimed at increasing opportunities for self-determination in individuals on the autism spectrum. Within the scientific community, there is a growing effort to promote rigorous research on treatment methods and outcomes within a social model that takes into account preferences and rights of individuals with ASD. Current approaches to treatment are mostly based on special education techniques. Different educational intervention programs vary in terms of the specific domains that are targeted (e.g., social skills versus self-management), the instructional techniques (e.g., directive teaching versus play-based approaches), and the overarching treatment goals (e.g., focus on ameliorating ASD symptoms versus focus on personal self-sufficiency). Some approaches use specific strategies to target a single domain or symptom (e.g., teaching how to communicate using alternative communication systems to compensate for language difficulties, or practicing social skills through adult-mediated social skills training groups). Other approaches involve comprehensive intervention programs, which target all areas of development. These programs usually involve the intensive engagement of the child in a planned educational intervention based on behavioral strategies, with operationalized instructional procedures, and a data collection system to facilitate progress and outcome measurement. Within this framework, different programs vary according to the specific curriculum, strategies, and underlying theoretical framework. For example, the Discreet Trial Training model (Lovaas, 1987) emphasizes a highly structured approach where predefined objectives are broken down in small, measurable units of behavior that are taught through systematic reinforcement, often using extrinsic rewards. In the Early Start Denver Model (Rogers and Dawson, 2010), instead, the focus is on the application of behavioral principles in joint play routines built on the child's spontaneous choices and motivation, with intervention goals organized around a behavioral framework (e.g., joint attention skills are taught before complex sentences, as joint attention precedes phrase speech in typical development). While positive effects have been documented for different focused and comprehensive programs, there is no evidence to indicate whether one treatment approach is more effective than others. Given the variability in learning profiles in ASD, it is likely that different children will benefit more from specific approaches according to their specific pretreatment characteristics; however, current knowledge on 'what works for whom' in autism is limited. Moreover, the degree of change that is attainable for individuals with ASD with autism, especially for those who are more severely affected, is not known. Initial claims of 'recovery' in response to behavioral treatment in half of the treated children have not

been substantiated by research. However, significant gains in cognitive, language, and adaptive skills appear to be possible for many individuals with ASD. Despite the differences in treatment approaches, a number of elements that are shared across most currently recommended programs appear to be particularly important for positive outcomes. These involve the enrollment of children in the intervention program as early as possible, the intensity of the program (at least 15–20 h per week, according to most guidelines), the use of systematic assessment procedures to define individualized sets of goals and monitor progress, and the involvement of parents.

Pharmacological treatment is sometimes used to target specific issues that can be associated with ASD, such as irritability and aggression; however, no medication appears to be effective in improving the core symptoms of autism.

A number of complementary/alternative medical treatments (i.e., treatments that are meant to be used alongside or as a substitute for standard treatments recommended by health professionals such as dietary interventions or supplements) are widely used, despite the lack of evidence for their efficacy.

Cultural Issues

The prevalence of autism is thought to be consistent across cultural groups, races, or countries and variations across sites disappear when accurate case identification methods are followed (Kim et al., 2011). Indirectly, the presence of autism parent organizations and advocacy groups across all continents suggests the universality of the constellation of behaviors originally described as autism by Leo Kanner. Nonetheless, the diagnostic classification manuals of choice, the availability of translated and validated diagnostic tools, as well as the beliefs hold by professionals, and the stereotypes attached to autism, which might influence symptom reporting by parents, vary across countries and play a major role in the diagnostic process. Moreover, the context where symptoms become apparent may be different in different cultural groups: for example, the ascertainment of qualitative impairments in communication should not overlook variations in language exposure, societal expectations, and communicative styles in parents (Grinker et al., 2011).

However, while it has been established that autism is a global public health concern, the vast majority of the research on the clinical presentation and neuropsychological profile of individuals with ASD has been carried out in Western countries. Therefore, it is not clear whether ASD features are affected by cultural differences, or whether ASD represents a culturally universal phenotype. This is particularly relevant with regard to neuropsychological and behavioral factors that are subject to cultural variations, such as, for example, the ability to detect items embedded within a more complex figure (known to be superior in Western versus Eastern cultures; Nisbett and Miyamoto, 2005) or the tendency to solve problems using experience-based versus rule-based strategies (known to be more pronounced in Eastern cultures; Norenzayan et al., 2002). A recent cross-cultural study (Koh and Milne, 2012) documented that, consistent with previous literature, British children with ASD outperformed their typically developing counterparts in tasks involving detection of shapes embedded in a complex figure – however, this was not the case in participants with ASD from Singapore, suggesting an impact of cultural variations in perceptual style of children with ASD. However, more cross-cultural research is needed to determine the degree to which cultural differences impact on symptom expression and neuropsychological functioning in ASD.

Rights/Policies/Advocacy Issues

Alongside the first advocacy campaigns of parents of children with disabilities to ensure free and appropriate public education (such as the Individuals with Disability Education Act in the United States), advocacy in the field of autism has historically focused on education and access to healthcare for children. In the United States, organizations such as the Autism Society of America and Autism Speaks have battled to gain autism insurance legislation to ensure access to services, and such legislation is now adopted or being considered by the majority of the states. In 2003, the Council of Europe has admitted the complaint presented by the umbrella organization Autism-Europe and recognized that the situation of the education provision in France constituted a violation of the right of persons with disabilities to independence, social integration and participation in the life of the community, as well as the right of children and young persons to social, legal, and economic protection (Articles 15 and 17 of the Social Charter). As there is a growing population of adults with autism (who would have went undiagnosed or misdiagnosed in the past), the main advocacy organizations as well as self-advocates are increasingly including in their agenda issues such as transition into adulthood, employment and housing, services for adults, and so on. Funding to services and research in the causes and treatment of autism has seen an unprecedented rise in the past decades, largely thanks to the efforts of these organizations. It is important to note though, that huge difference exists across nations: a recent report (Pellicano et al., 2013) has shown that the average research spend per autistic individual is 18 times higher in the United States than in the United Kingdom, and although no comparison data are available for the rest of the world, this gap is likely to be much wider.

Current Issues and Research Directions in Autism Research

Despite the tremendous increase in research in the last 20 years, autism remains an enigma. The complex phenomenology of autism raises a multitude of questions on the psychological and biological nature of social and emotional connectedness, language, the understanding of self and others' minds, as well as issues on appreciation of diversity, human rights and self-determination, stimulating empirical research and debate across a variety of disciplines. As it has become clear that this disorder does not result from a single dysfunction or pathological pathway, current research is focusing on understanding the interplay of biological, neuropsychological, and environmental factors. One critical issue that is still poorly understood is the interrelation between the seemingly unrelated symptoms of autism and their relation to the other features that are

present in some but not all individuals on the spectrum (e.g., epilepsy, special talents). Research on factors underlying clinical heterogeneity should also inform research on the variability in treatment response in this population, with the potential to identify profiles of responders and nonresponders to available treatment programs. The nature of ID in ASD is another important issue: why do many individuals with ASD (50%) have a cognitive delay, while some have an above average IQ? What is the link between symptoms of autism and cognitive development? Current research is addressing these issues using a variety of approaches, but answers to these questions remain elusive.

Advances in technology in the last decade (e.g., neuroimaging techniques) have offered unprecedented opportunities to investigate brain functioning in ASD and brought to promising research leads, including evidence for atypical functioning of the 'social brain network,' abnormalities in the mirror neuron system activity, as well as evidence for disturbances in neural connectivity (e.g., the synchronization between different brain regions). However, findings in this area are often inconsistent, and research has thus far failed to identify neural correlates of ASD that are universal, specific, and unique to this condition.

A full understanding of the processes underlying ASD symptoms is made difficult by the fact that the processes underlying typical development of social–emotional reciprocity and their role in cognitive, language, and personality development are poorly understood. Therefore, research advances in the biology and neuropsychology of typical social and emotional development have the potential to facilitate the understanding of autism. Conversely, research in autism has the potential to crucially inform knowledge in medical, biological, social, and behavioral sciences.

Autobiographical Memory

This article is a revision of the previous edition article by M.A. Conway, volume 14, pp. 9563–9567, © 2001, Elsevier Ltd.

Abstract

When we use the word 'memory' in everyday conversation, we are usually referring to a memory of a specific event, whether it be yesterday's lunch meeting, last year's graduation ceremony, or the snowstorm that blanketed our town when we were young. At times, we might recall exceptionally powerful memories, such as the 11 September attacks or a robbery that happened right in front of our eyes. We might reminisce on happy events or ruminate on sad ones, and we might find ourselves lost in memories of our youth. All these are examples of autobiographical memory – in other words, memories of the events of one's life. More than a century of research has led to fascinating discoveries about the distribution of memories across the life span and the factors that affect the vividness and intensity of recall.

What Is Autobiographical Memory?

The study of autobiographical memory is broad in scope, and researchers in this field often investigate topics such as flashbulb memory, eyewitness testimony, the development of autobiographical memory in children, and the loss of autobiographical memory as a result of neurological disorder. This encyclopedia already contains articles on all of these topics, so we will not revisit them here. Instead, we will concentrate on basic research in autobiographical memory, with brief detours to touch on otherwise-uncovered topics such as autobiographical recollection in people with mood disorders.

First, however, we should define what is meant by 'autobiographical memory.' As is common in psychological research, different researchers define the term in different ways. According to many researchers, a defining feature of autobiographical memory is *recollection* – that is, the sense that one is reliving or reexperiencing the original event (see Brewer, 1996, for discussion). This might make it sound as though autobiographical memory is a kind of episodic memory, and some researchers do define the term that way (Rubin, 1998, 2006).

Other researchers draw a distinction between *autobiographical event memory* and *autobiographical facts* or *personal semantic memories*, such as one's childhood address (Kopelman et al., 1989; Levine et al., 2002). Memories like these can be retrieved without having a specific event in mind, and thus they do not seem to qualify as episodic. They seem more like a form of semantic memory, but they differ in one key way. Semantic memory is fairly consistent across people (at least within a language and a culture), but personal semantic memories are not: most of the people reading this article will have a similar idea of what a house is, but your childhood address is almost certainly different from mine. Thus, personal semantic facts have an autobiographical aspect to them even though they are not episodic.

Conway and colleagues (e.g., Conway, 2001; Conway and Pleydell-Pearce, 2000) have developed a hierarchical model that incorporates several different kinds of autobiographical information. *Lifetime periods* are distinct periods with beginnings and endings – for instance, "when I was in school," "when I worked for *x*," or "when I was dating *y*." *General events* are more specific than lifetime periods; they include experiences that span a relatively long period (a family vacation in 1997) as well as repeated events (for instance, Tuesday lunches with my best friend; Neisser's (1981) term "repisodic memory" covers a similar idea). *Event-specific knowledge* consists of vivid and detailed sensory information, often visual, that is drawn from individual events and is thus episodic in nature. In Conway's view, all these levels are autobiographical, and retrieval can proceed up and down this hierarchy as appropriate to generate a rich autobiographical memory that is grounded in a person's self-knowledge.

Nonepisodic autobiographical memories obviously have everyday importance – we all need to be able to remember our home address, for instance. They are also relevant in clinical situations: people with semantic dementia, for instance, are often unable to retrieve event-specific knowledge, even though they can retrieve general events (e.g., Westmacott et al., 2001). For the most part, however, research has focused on episodic autobiographical memories – memories of events – and we will focus on them for the remainder of the article.

A Classic Example

The archetypical autobiographical memory comes from Marcel Proust's (1922/1934) *A la recherche du temps perdu*, variously translated as *Remembrance of Things Past* or *In Search of Lost Time*. When the narrator takes a bite of *petite madeleine* soaked in tea, he is struck with a sense of inexplicable joy, and then, a few bites later, he is transported into the past:

> [S]uddenly the memory returns. The taste was that of the little crumb of madeleine which on Sunday mornings at Combray…my aunt Léonie used to give me, dipping it first in her own cup of real or of lime-flower tea…[I]mmediately the old grey house upon the street, where her room was, rose up like the scenery of a theatre to attach itself to the little pavilion, opening on to the garden, which had been built out behind it for my parents…and with the house the

> town, from morning to night and in all weathers, the Square where I was sent before luncheon, the streets along which I used to run errands, the country roads we took when it was fine….[S]o in that moment all the flowers in our garden and in M. Swann's park, and the water-lilies on the Vivonne and the good folk of the village and their little dwellings and the parish church and the whole of Combray and of its surroundings, taking their proper shapes and growing solid, sprang into being, town and gardens alike, all from my cup of tea. (Proust, 1922/1934: p. 36)

Psychologists like to cite this memory because it illustrates many of the key features of autobiographical recall. The first few steps come involuntarily, triggered by the taste of the petite madeleine. The full memory does not spring to mind at once; it slowly and deliberately unfolds into a story. The narrator feels transported back in time, he sees a series of vivid visual images, he remembers the setting, and then he feels the emotions he felt then. In short, he is *recollecting* his days at Combray – mentally reliving them as though he were experiencing them once more.

Measuring Autobiographical Memory

Before discussing these features in more detail, we should describe how researchers measure autobiographical memory. This is not as simple as it might seem, at least if one wants to measure it in a rigorous and reliable way.

Ever since Ebbinghaus, most memory experiments have followed the same general pattern. Researchers compile a set of stimuli, such as a list of nouns or a series of images. These stimuli are carefully selected so that they have certain desirable properties. In verbal learning experiments, for instance, the researchers might select words with a particular degree of frequency, imageability, and length. They can then administer each word to participants for a precise amount of time, repeat it as often as they like, and measure retention at set intervals. Much of the experiment can be timed to the millisecond, if needed, allowing for a great degree of experimental control.

For the most part, those of us who study autobiographical memory are unable to do any of these. We generally have no control over the original experience, and, in most cases, we will be asking about different experiences from each participant. We cannot be certain how often the participant rehearsed the experiment (whether by thinking about it, talking about it with others, or writing it down in a diary), and we have only the participants' best estimate of when the remembered event occurred. In fact, for the most part, we have no way to know whether the remembered event actually took place at all; for all we know, the participant could be misremembering, confabulating, or just plain making something up.

There are a few exceptions. In diary studies (e.g., Barclay and Wellman, 1986) and studies of flashbulb memory (e.g., Talarico and Rubin, 2003), we have more insight into some aspects of the original events. In some cases, participants are placed in contrived situations (St. Jacques and Schacter, 2013), as is common in studies of eyewitness testimony (Loftus and Palmer, 1974). In clinical situations, investigators sometimes try to have memories verified by a spouse, but this is problematic as well: Spouses do not always agree even in the best of circumstances, and when two people disagree, one can never quite be sure which (if either) is actually correct.

These challenges have led some authors to suggest that carefully designed laboratory experiments are a better way to investigate memory. Others feel that the study of real-world phenomena is critical, no matter how messy it might be. This debate reflects the long-standing tension between naturalistic, ecologically valid psychology and traditional laboratory-based psychology (see Neisser, 1978; Banaji and Crowder, 1989, for discussion.) Wherever one stands on this issue (and it seems to be largely a matter of taste), it is clear that autobiographical memory research must use research methods that are different from the usual verbal learning paradigms.

Thus most measures of autobiographical memory do not focus on accuracy, but rather on aspects such as phenomenological properties, the efficacy of certain cues, or (in the case of amnesia) whether the individual can remember anything at all. In the Galton–Crovitz paradigm, for instance (Galton, 1879; Crovitz and Schiffman, 1974), participants are presented with a series of cue words such as *tree* or *candy* and asked to come up with a memory associated with each. The Autobiographical Memory Test (Williams and Broadbent, 1986) takes this approach a step further by using emotionally valenced words to elicit memories. Researchers can use these tasks to assess how many memories people recall from a particular period and how detailed those memories seem to be; they can also assess how different kinds of people respond to positive and negative cues (see the section on depressive disorders and memory for more details). They can add on a questionnaire that asks people to rate the phenomenological properties of the memory (Rubin et al., 2003; Johnson et al., 1988), allowing them to explore the relations between these properties.

The Galton–Crovitz test is straightforward and easy to use, but as several authors have noted, it is somewhat artificial (Kopelman et al., 1989). Furthermore, it provides very little in the way of retrieval support. The link between cue word and memory is not always obvious, so participants must rely on executive functioning to search for and locate an appropriate memory. Consequently, poor performance on the task might actually reflect a deficit of executive function rather than poor autobiographical memory.

The Autobiographical Memory Interview (Kopelman et al., 1989) tries to address this problem by taking a more structured approach. It divides the participant's life span into three periods – childhood, early adulthood, and recent – and asks people to come up with autobiographical events and personal semantic memories from each. The test manual provides a detailed scoring method, and the results can be compared to established norms. In addition, the manual specifies the precise memories the participant is to give (for instance, a wedding). In this way, it provides a greater degree of retrieval support, presumably reducing the demand on executive function. At the same time, these constraints are not always desirable: If one wants to investigate which of a participant's memories are most vivid, for instance, this test would not be as appropriate.

The Autobiographical Interview (Levine et al., 2002) attempts to balance these two approaches by varying the

amount of retrieval support. Participants are asked to generate a memory from each of five time periods. For each memory, participants are first asked to speak about each event freely, that is, they are provided with very little retrieval support. Next, the experimenter provides a *general probe* (for instance, by asking whether the participant can remember anything else). Finally, the participants are given a semistructured interview that asks about the specifics of the event, the time and place at which it occurred, and various other details. The resulting memories can be scored both for episodic and semantic components, and one can gain some insight into a particular individual's need for retrieval support. As always, there is a price to be paid for this approach: only five memories are obtained, and even so the test can be quite long.

Each of these tests has been used to discover interesting and important results, and each has its advantages and disadvantages. As with much of psychology, 'it depends on how you measure it': the results you get can vary with the measure you select. Ultimately, different tests are appropriate for different circumstances, and the choice of test will depend on what exactly a researcher is trying to measure.

Aspects of Autobiographical Memory

Distribution of Memories across the Life Span

Proust's vivid memory illustrates another aspect of autobiographical memory, namely, the persistence and vividness of memories from youth. For most forms of memory, the retention curve takes the form of a power function: a substantial amount of information is lost upfront, but a core of information lasts much longer (Rubin and Wenzel, 1996). As **Figure 1** shows, however, the retention function for autobiographical memory takes a different form. The data were generated using the memories of 70-year-olds. The *x*-axis shows the decade in which the event occurred, and the *y*-axis shows the percentage of memories from that decade, excluding the last year.

Figure 1 Typical distribution of memories across the life span. Reproduced from Rubin, D.C., Schulkind, M.D., 1997. The distribution of autobiographical memories across the lifespan. Memory and Cognition 25, 859–886.

The right side of the curve shows the normal retention function, and on the left side, there are few, if any, memories from before the age of 3 (this is called childhood amnesia and is covered in more detail in Childhood Memories). Something unusual is happening in the middle, however: people recall a disproportionate recall of events from ages 15 to 25.

This phenomenon is called the reminiscence bump, and it is one of the most reliable phenomena in autobiographical memory research (Rubin et al., 1986). The precise location of the peak varies a bit from study to study, but is always somewhere in this period. It occurs when participants are asked about vivid memories (Fitzgerald, 1988), important memories (Fitzgerald, 1996), olfactory-cued memories (Rubin et al., 1984), involuntary memories (Berntsen and Rubin, 2002), and happy memories (Berntsen and Rubin, 2002). It occurs when people are asked for their life stories (Fromholt and Larsen, 1991) or which memories should go into a book about their life (Fitzgerald, 1996). It does not seem to occur for negative memories, however (Berntsen and Rubin, 2002; Rubin and Berntsen, 2003), a point to which we will return.

Why does the reminiscence bump occur? One straightforward explanation involves neurocognition: neural and cognitive function is thought to be at the peak during this period, so the bump might reflect that encoding is optimal at this point in development. Another explanation involves novelty: this period of life involves many firsts (first romantic relationship, first real full-time job, first time living independently, etc.), and novel information tends to be more memorable (Rubin et al., 1998). Other explanations focus on social or developmental factors. Fitzgerald (1996), for instance, has attributed the reminiscence bump to the development of identity in adolescence and young adulthood. Since events during this period are particularly important for identity function, it makes sense that they would be disproportionately included in the story of one's life. Similarly, Conway and colleagues (Conway and Haque, 1999; Rathbone et al., 2008) attribute the bump to the formation of highly self-relevant memories. In support of several of these views, a few studies have reported a second bump for momentous or transformative events, such as immigration to a new country (Schrauf and Rubin, 1998, 2001) or a struggle for national independence (Conway and Haque, 1999).

While each of these factors might contribute to the reminiscence bump, they cannot entirely explain the phenomenon. Most of these hypotheses (except perhaps the novelty hypothesis) would predict a bump for negative memories, but no such bump is found. Why not?

Berntsen and Rubin (2002, 2004) have suggested that *life scripts* might explain the reminiscence bump. They define a life script as a sequence of events that typically happens to an individual living in a particular culture. They further describe it as an *idealized* life story, meaning that it will exclude common but unpleasant events such as a divorce, the loss of a job, or the early death of a parent. Several lines of evidence suggest that life scripts help structure recall. When adults think about the likely life story of a typical adult in their culture, they tend to list a disproportionate number of events from the 'bump' period (e.g., Berntsen and Rubin, 2004). Similarly, Bohn and Berntsen (2011) asked children to describe their future lives and found

that a disproportionate number of events come from early adulthood. These findings are consistent with the idea that the life script helps structure autobiographical recall by putting greater emphasis on positive events in early adulthood.

Phenomenological Properties of Autobiographical Memory

As we noted above, several autobiographical memory tests can be used to measure the phenomenological properties of autobiographical memory – for instance, its narrative coherence, the vividness of its imagery, the intensity and valence of the emotions it evokes, and so on. Based on data collected with these measures, Rubin and colleagues (Rubin, 1998; Greenberg and Rubin, 2003) have developed a basic-systems model of autobiographical memory that suggests that autobiographical memory is a high-level process that draws on information from a number of other processes, including sensory imagery, emotion, language, narrative coherence, and executive function.

Here we focus on visual imagery, which has been identified as one of the most important of these processes (Brewer, 1996; Brewer and Pani, 1996). In previous work, we used the Autobiographical Memory Questionnaire to investigate the relationship between visual imagery and reliving (Rubin et al., 2003). We found that the intensity of visual imagery during recollection strongly predicted the extent to which participants felt that they were reliving an event. In fact, visual imagery seemed almost necessary for this feeling of reliving: Fewer than 2% of memories were recalled with both a strong sense of reliving and weak visual imagery. D'Argembeau and van der Linden (2006) examined individual differences in visual imagery and showed that the vividness of participants' visual imagery predicted the amount of sensory detail and temporal information in the memory but did not predict the intensity of the memories or their personal importance. Finally, impairments of visual imagery have been associated with memory impairments (e.g., Greenberg and Rubin, 2003), further supporting the idea that visual imagery has a fundamental role to play in autobiographical recall.

Olfactory Cuing of Autobiographical Memory

Proust's description of the memory evoked by the petite madeleine has led a number of researchers to investigate the connection between odor and autobiographical memory. (As a side note, it is not at all clear how this happened. As the quotation above shows, Proust's narrator's memory was triggered by the *flavor* of the madeleine, including its texture and taste, rather than the smell. Taste and smell are certainly linked, in part through the phenomenon of retronasal smell, but most of the studies following Proust have *only* used olfactory cues.) Odor cues can clearly evoke autobiographical memories (Rubin et al., 1984; Larsson and Willander, 2009), and they seem to be particularly good at eliciting vivid and intense memories: odor-cued memories are more emotional (Herz and Cupchik, 1995; Rubin et al., 1984) and more detailed (Chu and Downes, 2002). Furthermore, odor-cued memories tend to be older (Willander and Larsson, 2006) and have not been rehearsed as often (Rubin et al., 1984; Willander and Larsson, 2006). In short, olfactory stimuli seem perfectly tailored to trigger the recollection of a Proustian sort of memory.

Overgeneral Memory and Depression

Most of these studies were trying to find the factors that led to rich and vivid autobiographical memories. Another group of researchers has taken a different approach and has investigated memories that are overly general and devoid of detail. This might seem like a strange topic to study, but it turns out to be important for a very simple reason: the inability to retrieve detailed autobiographical memories is very common in people with various forms of depression and other psychiatric conditions (see Williams et al., 2007, for a review).

Williams et al. (2007) have characterized overgeneral memory as a tendency to summarize past events in categories rather than giving a specific memory, even when asked to be as specific as possible. For example, when asked to recall a specific event in response to the cue word *lonely*, a person without depression might say, "I really felt lonely last Friday when nobody turned up at the party," whereas a person exhibiting overgeneral memory might say, "I feel lonely on the evenings that my wife goes out working" (Hermans et al., 2008: p. 669).

According to several studies, depressed individuals who tend to retrieve overgeneral memories have a poorer prognosis than those who do not (e.g., Brittlebank et al., 1993; Williams et al., 2007). They continue to generate overgeneral memories even when they are not in the midst of a depressive episode (Williams and Dritschel, 1988; Mackinger et al., 2000). Similarly, the production of overgeneral memories generally predicts later depression (Gibbs and Rude, 2004).

Researchers have proposed several theoretical explanations of overgeneral memory (Conway and Pleydell-Pearce, 2000; Williams et al., 2007). First, people might essentially train themselves to retrieve overgeneral memories because it helps them avoid remembering detailed and emotionally painful memories (Conway and Pleydell-Pearce, 2000). Second, people with depression can easily fall into rumination, a state in which they constantly reflect on their depressive symptoms. The connection to overgeneral memory is straightforward: When all mental roads lead to rumination, specific memories are very difficult to retrieve. Third, some evidence suggests that people with depression might have poorer executive function (or might just exert less effort at any cognitive task), which would make it more difficult for them to search for and assemble a detailed memory (Conway and Pleydell-Pearce, 2000; Williams et al., 2007).

Any or all of these factors could induce an individual to retrieve overgeneral memories. Furthermore, Williams et al. (2007) have proposed that these tendencies may grow more severe over time because of mnemonic interlock. That is, as people retrieve overgeneral memories, those memories are rehearsed more and more, making them easier to retrieve than more detailed memories. Recent studies have shown that there are ways to alleviate the problem. Mindfulness-based cognitive therapy can mitigate overgeneral memory as well as depression (Williams et al., 2000; Neshat-Doost et al., 2013), perhaps because they

encourage people to focus on specific aspects of their thoughts and experiences.

Cultural Differences in Autobiographical Memory

An intriguing and relatively recent line of research has revealed cultural differences in autobiographical recall. According to Ross and Wang (2010), people from Western and Eastern cultures tend to describe their memories in different ways. People from Western cultures tend to emphasize individuality and the development of a unique identity, whereas people from East Asian cultures tend to place more emphasis on their role within a larger society. In accordance with this view, people of European descent tended to rate their memories as more personally important than Chinese people did (Wang and Conway, 2004). An examination of the content of autobiographical memories yields similar findings. People of Asian descent tend to report more memories of events involving other people (see Ross and Wang, 2010, for review), and they are more likely to visualize memories from a third-person perspective than people of European descent are (Cohen and Gunz, 2002).

There are other differences as well. Westerners tend to retrieve more autobiographical memories in a variety of tasks (Wang, 2009), and their oldest memories tend to be a bit older (e.g., MacDonald et al., 2000). Interestingly enough, this difference can be eliminated by priming the European participants to focus on group affiliation (or, for that matter, priming the Asian participants to focus on themselves as unique individuals), suggesting that the culture to which they belong creates a default 'mindset' that guides recall (Wang and Ross, 2005). All these findings come with an important caveat: As Ross and Wang (2010) note, the vast majority of studies have compared Asian and European cultures, meaning that differences between other cultures remain relatively unexplored.

Involuntary Memory

So far, most of the studies we have discussed involve voluntary recall – participants were asked to make a deliberate effort to retrieve a specific autobiographical memory. Yet, much of the time – perhaps most of the time – our memory does not work in this way. As with Proust's narrator, our memories often come to mind unbidden, without any apparent cue or any conscious attempt to recall. These are known as *involuntary memories* (Berntsen, 2009), and in the past two decades, they have received an increasing amount of attention in the cognitive psychology literature.

The study of involuntary memories is not new. Berntsen (2009) has noted that the idea goes back at least to Ebbinghaus (1885/1964), who distinguished between non-conscious memories, voluntary memories, and involuntary memories. For the most part, however, psychologists focused on purposeful retrieval and the construction of memory, with some authors suggesting that involuntary memory was not amenable to scientific study at all (Miller, 1962). The problem is straightforward: it is hard to ask participants to conduct a deliberate search for involuntary memories, because then they would not be involuntary at all.

Nevertheless, recent studies have led to new discoveries about this type of memory. Many of these studies used a diary method, in which participants are given a diary and asked to answer a series of questions whenever they realize that an involuntary memory has sprung to mind. These studies show that involuntary memories are quite common. Typically, they are evoked by some kind of identifiable cue, whether from the outside world or the participant's own thoughts (e.g., Berntsen and Hall, 2004; Mace, 2004; Schlagman et al., 2007). Their distribution tends to follow the shape of the forgetting curve (Berntsen and Hall, 2004); the reminiscence bump is still present when older adults are tested, and it is still limited to positive memories (Berntsen and Rubin, 2002; Schlagman et al., 2007). Moreover, the event tends to be positive (Hall and Berntsen, 2008; Walker et al., 2003), as with voluntary autobiographical memory.

There are also intriguing differences between involuntary and voluntary memories. Most studies show that involuntary memories are more likely to refer to specific and distinct episodes (e.g., Berntsen and Hall, 2004); moreover, they do not show the usual decline in specificity with age (Schlagman et al., 2007). They also tend to be more emotional (Berntsen and Hall, 2004). Nevertheless, Rubin and colleagues (2008) found that these memories were less fundamental to a person's life story than voluntary memories were. Berntsen (2009) has suggested that these findings can be reconciled by looking at some of the differences in which these memories are cued. For instance, voluntary memory requires a deliberate search, whereas involuntary memory is elicited by a cue encountered by happenstance. Almost by definition, we are more likely to conduct voluntary searches for personally important memories, but involuntary memories can be about anything. Similarly, a specific and unique episode might be hard to search for voluntarily, but when the right cue is encountered, it will spring to mind. Thus, involuntary memories complement voluntary memories in many ways, forming a fundamental but still-understudied aspect of autobiographical recall.

Neuroimaging of Autobiographical Memory

Cognitive neuroscience has built on this research by using functional neuroimaging to uncover the neural correlates of autobiographical memory (for a review, see St. Jacques, 2012). These studies have generally shown that autobiographical retrieval involves a sequence of activation across the prefrontal cortex, medial temporal lobe, and posterior cortices. Prefrontal activation occurs throughout the medial and lateral prefrontal cortex. Medial activation is generally taken to reflect the processing of self-relevant information, whereas lateral activation is thought to reflect the need to search for an autobiographical memory and maintain it in mind. Within the medial temporal lobe, the hippocampus is thought to mediate vivid recollection by coordinating activity in posterior cortices; amygdala activation reflects the emotional content of the memory. Activation in occipital and retrosplenial regions presumably reflects the vivid visual imagery that is so often associated with autobiographical recall.

Conclusion

All these studies have provided important insights about the ways in which we remember our lives. Dozens of studies have shed light on the durability of memories from early adulthood, the effects of different kinds of cues, and the ways that memories differ across cultures. Other studies have explored the effects of different forms of mental illness, and some have even managed to explore involuntary memory; in the past decade or so, researchers have begun to examine the neural systems that underlie this form of recall. Autobiographical memory will no doubt remain a challenging phenomenon to study, but our efforts so far have clearly paid off.

Autobiographical Memory during Early Childhood and Cultural Variations

Qi Wang and Robert C Blenis, Cornell University, Ithaca, NY, USA

Abstract

The development of autobiographical memory is foreshadowed by many early prerequisite skills. It is not an all-or-none phenomenon but involves a gradual incremental process. Young children's memories are initially fragmentary and incoherent. Over the preschool years, their memories show increasing endurance, temporal coherence, complexity, and elaboration as a result of multiple contributing factors. These factors include neurological maturation, language acquisition, development of a sense of self, and participating in adult-guided memory conversations. Evidence emerging from sociocultural approaches further shows that cultural beliefs and the associated narrative practices shape the quantity and quality of autobiographical memory throughout early childhood.

Introduction

Young children often exhibit impressive abilities to remember things that occur in their lives. Memory for distinct personal experiences, namely, autobiographical memory, encompasses knowledge of the self and is critical for personal identity and psychological well-being (Conway and Pleydell-Pearce, 2000; Pillemer, 2009). The development of autobiographical memory is foreshadowed by many early prerequisite skills and takes place rapidly across the preschool years (Bauer, 2007; Nelson and Fivush, 2004). Once toddlers develop general memory skills, rudimentary language, and an emerging cognitive sense of self, they become able to recall fragmentary information about their past experiences with help from adults. With further neurological maturation, language and cognitive growth, and particularly through participation in memory conversations with adults, preschoolers remember personal event information with increasing endurance, temporal coherence, complexity, and elaboration. Furthermore, children's memories of personal experiences are intricately shaped by cultural beliefs and mnemonic practices of the community (Wang and Ross, 2007). During the myriad of daily exchanges with their parents and others, children come to construct personal life stories that reflect both their cultural knowledge and idiosyncratic characteristics.

Autobiographical Memory Development in Early Childhood

Development of Long-Term Memory

The development of autobiographical memory in early childhood is a continuous multifaceted process. First, infants must be able to retain event information over an extended period of time. Arguably, the capacity for long-term memory may be present in very early infancy, at 2 months of age, as reflected in operant conditioning paradigms, such as the mobile reinforcement task, the high-amplitude sucking procedure, or the train task (Reese, 2009). However, a general consensus among researchers is that the ability to form long-term memories emerges at about 6 months of age, as measured in deferred imitation paradigms (Bauer, 2007). In these paradigms, an infant observes an experimenter interacting with novel objects. After a delay, infants are presented with the same objects they saw the experimenter interact with earlier. If the infant imitates the experimenter's earlier interactions with the objects, they are believed to have developed long-term memory. At 6 months, infants can reproduce specific actions after a delay of 24 h, and by 9 months, infants can recall actions of multistep sequences over delays as long as 5 weeks. Still, long-term memory ability is fragile and unreliable in the first year. Infants often require multiple experiences of the to-be-remembered actions in order to recall these actions later, and there exists a wide range of individual differences. The ability to recall sequences of actions improves dramatically over the course of the second year, where older infants can remember complex event information over delays of several months and even a year (Bauer, 2007).

The Self and Autobiographical Memory

Early long-term memories are not '*auto*biographical,' however, until a cognitive sense of self emerges to connect the past experiences to 'me.' The cognitive sense of self – a rudimentary form of self-concept – emerges at about 18–24 months, as indicated by passing a mirror self-recognition test. It is considered a critical precursor for the emergence and development of autobiographical memory (Howe, 2003). With the self in place, personal event information can now be represented and organized in a structured fashion and, consequently, becomes more accessible for later retrieval. Harley and Reese (1999) found that children's self-recognition skills at 19 months uniquely predicted their ability to remember autobiographical events at 32 months, and children who recognized themselves in the mirror at earlier ages developed autobiographical memory at a faster rate than did children who recognized themselves at later ages.

The self continues to develop and enrich over the preschool years, providing children with a sense of psychological continuity in time and enabling them to construct personally meaningful, causal connections among events (Povinelli, 1995; Welch-Ross, 2001). As a result, event representation is gradually transformed from a static collection of isolated episodes to a temporal–causal organization of life stories and, thus, an enduring autobiographical memory system. Notably, the self is only a necessary but insufficient factor for autobiographical

memory development. Among the many other factors that accompany the development of autobiographical memory is children's burgeoning language proficiency.

Language and Autobiographical Memory

Language provides tools for both memory representation and expression (Nelson and Fivush, 2004). Simcock and Hayne (2002) found that children cannot translate prelinguistic experience into language. In their study, young children participated in a unique event and their memories were assessed 6 months or 1 year later. There was not a single instance in which children verbally retrieved information about the event that was not part of their productive vocabulary at the time of encoding. In other words, if the children could not express something verbally the time when the event took place, they did not express it verbally in recall, even though their language skills had improved dramatically.

Although memory may not depend on language, linguistic representation and reinstatement of event information may make the information more enduring (Nelson and Fivush, 2004). Language can be considered to compress the multimodal sensory inputs that form the basis of autobiographical memory into associations between a word or phrase, its meaning, and remembered experience. Language may further serve as retrieval cues to facilitate recollection. As children's language proficiency increases, they can use a wider range of linguistic cues to aid recall and process information more efficiently. Consequently, the expansion of children's verbal repertoire is followed by an increase in the coherence and endurance of their autobiographical memory (Hayne, 2004).

Memory Sharing and Parental Conversational Styles

In addition to serving as a medium for memory representation and expression, the developing language skills allow children to participate in memory conversations with others, particularly parents, which is considered a critical factor for the development of autobiographical memory (Nelson and Fivush, 2004; Reese, 2009). Through memory sharing, parents model to children how to organize and communicate past experiences in narrative forms, which facilitates long-term retention of the event information. Parents also provide evaluations (e.g., 'That's a fun experience') that help children derive personal meanings from past experiences, making the experiences more memorable. Furthermore, memory sharing highlights the social significance of autobiographical memory, thus showing children why the past is worth remembering.

Children begin to participate in joint conversations of the past before the end of the second year, at as early as 15–17 months of age. While their contributions are initially fragmentary and difficult to understand, their recollections are gradually shaped into more vivid, understandable narratives over the preschool years as their parents provide evaluations and feedback and situate the past in personally meaningful contexts (Nelson and Fivush, 2004; Reese, 2009).

Furthermore, the way that parents structure memory conversations is an important variable that affects preschool children's developing autobiographical memory (Fivush et al., 2006). High-elaborative parents often ask open-ended questions, embellish the event under discussion with rich details, and provide evaluative feedback to scaffold and encourage children's participation in the conversation. Low-elaborative parents, in contrast, often attempt to elicit specific answers from children by simply repeating pointed questions and rarely comment on children's responses. These stylistic differences in parent–child memory sharing have both concurrent and long-term effects on children's autobiographical memory: children of high-elaborative mothers typically remember more details and discuss the past with greater elaboration than children of low-elaborative mothers by the end of the preschool years (Fivush et al., 2006; Nelson and Fivush, 2004; Reese, 2009). The effect of early maternal conversational styles on autobiographical memory recall persists through adolescence (Jack et al., 2009).

Other Contributing Factors

There are many other factors that may play important roles in the development of autobiographical memory in early childhood. For example, neurological maturation, particularly developments in medial temporal and cortical structures, enables more efficient consolidation of event information following the initial encoding, thus making the information more enduring (Bauer, 2007). Knowledge about emotion situations helps children understand the personal significance of past events, experience appropriate emotions during the events, and organize the event information in a structured fashion, thereby facilitating the retention of and access to the event memories over the long term (Wang, 2008). An evaluative self-awareness, as reflected in children's understanding of norm violations (e.g., broken toys), use of evaluative words (e.g., 'dirty'), and references to competencies (e.g., 'I can do it'), may serve as a self-referential frame that children use to represent not only personal events as experienced but also their subjective attitudes toward the events (Welch-Ross, 2001). In addition, theory of mind, metamemory, narrative skills, and knowledge of time may all contribute to the development of autobiographical memory in early childhood (Nelson and Fivush, 2004). Given all the contributing factors, as children grow older, they are able to remember more details from their personal experiences, retain the details for a longer period of time, require less support to retrieve the information at recall, focus more on the distinctive aspects of past events, and ascribe more readily personal meaning to the events (Bauer, 2007).

Childhood Amnesia

While children as young as age 2 or 3 years are able to remember autobiographical events for a considerable period of time, most adults do not remember any events that occurred before age 3 years and exhibit a continued scarcity of memories for events occurring between ages 3 and 5 years (Bauer, 2007; Pillemer and White, 1989). This phenomenon is referred to as childhood amnesia or infantile amnesia. It could be argued that childhood amnesia is because events from early childhood occurred so long ago that they become forgotten or inaccessible. However, if the events recalled from different

periods of life are plotted by the time of occurrence, fewer events are recalled from early childhood than would be expected if forgetting occurred linearly as a function of time (Bauer, 2007; Nelson and Fivush, 2004).

Typical studies of childhood amnesia examine adults' recollections of events that occurred in childhood. Recent approaches that examine children's recollections of early childhood have shown that before age 8 or 9 years, children can still recall a great deal of information about salient events that occurred at ages 2 and 3 years (for a review, see Peterson, 2012). The ability to access very early memories decreases with age, such that younger children can recall memories from an earlier age than older children. It appears that early memories vanish or become inaccessible at some point as children grow older. On the other hand, memories for events that occurred after the period of childhood amnesia (after age 5 years) become increasingly well retained, consolidated, and long lasting, as a result of the interactive contribution of a variety of neurological, cognitive, linguistic, and sociocultural factors that were discussed earlier. The emergence of autobiographical memory and the offset of childhood amnesia represent two sides of the same coin.

Cultural Influences on Early Autobiographical Memory

Cultural Views of the Self

Cultural ideologies and practices have pervasive effects on the development of autobiographical memory. In particular, the conception of selfhood differs markedly across cultures (Markus and Kitayama, 1991). In Western, particularly North American, cultures that embrace individuality and autonomy, the self is defined primarily by individuals' inner attributes and qualities independent of social others and contexts – an autonomous self. In contrast, in East Asian cultures such as China and Japan that give prominence to interpersonal harmony and collectivity, the self is largely defined by one's social stratification and responsibility – a relational self.

Given the executive role of the self in modulating autobiographical remembering (Conway and Pleydell-Pearce, 2000), different cultural views of the self may have profound effects on the development of autobiographical memory (Wang and Ross, 2007). An autonomous self, valued in Western cultures, may motivate individuals to attend to, encode, and retain information of events that happened to 'me' and further drive the early development of an organized, articulated, and durable autobiographical memory system. Also, in this cultural context, autobiographical memories may focus on unique personal experiences, especially specific, one-moment-in-time episodes that are unique to the individual and focus on the individual's own roles, feelings, and perspectives (e.g., 'the time I won the spelling bee competition'). In contrast, a relational self, valued in many Asian cultures, may prioritize instead the retention of knowledge – not necessarily in the form of memory – that is critical for social harmony and collective solidarity. The development of a structured memory system for one's own experiences may not be accentuated. When remembering the past, individuals may focus on information about group activities and social interactions. Individuals may also attend to generic routine events (e.g., 'going to parties'), which generally serve to direct one's behavior in particular, oftentimes social, situations (Wang, 2013).

In line with this theoretical analysis, studies have shown that compared with Asian children, European and Euro-American children as young as age 3 or 4 years are able to access more distant and detailed autobiographical memories, retrieve more frequently unique, one-time episodes (as opposed to generic events), and focus more on their own roles and predilections (for reviews, see Wang, 2013; Wang and Ross, 2007). For instance, Wang (2004) examined autobiographical memory as well as self-concept in 180 European American and Chinese preschoolers, kindergartners, and second graders. Children were asked to recount personal events such as a recent time when they did something special and fun. They also answered open-ended questions that elicited self-descriptions. Across all age groups, Euro-American children provided lengthier, more detailed, and more emotionally elaborate memories than did Chinese children. American children also focused more on their own roles, preferences, and feelings (e.g., 'I liked the birthday present,' and 'My mom didn't let me go out but I did anyway') and recalled more specific episodes than Chinese children. The Chinese children, in contrast, often recalled past experiences that centered on social interactions and daily routines. Furthermore, consistent with cultural values and beliefs about the self (Markus and Kitayama, 1991), Euro-American children more often described themselves in terms of personal attributes and predilections (e.g., 'I am smart' and 'I like hockey') than Chinese children, who talked more about social categories and relationships ('I am a child' and 'All my friends like me'). The cultural differences in autobiographical memory and self-concept increased in magnitude with age, presumably reflecting the effect of socialization and enculturation. Importantly, across the entire sample, children who exhibited a greater autonomous sense of self also provided lengthier and more self-focused memory accounts, independent of culture and age.

There is additional evidence that cultural influences on autobiographical memory are mediated by cultural self-views (Wang, 2013; Wang and Ross, 2007). For instance, Wang (2006) examined the question of whether cultural differences in memory accessibility are driven by differing self-concepts that focus on autonomy versus relatedness. Three-year-old children from Chinese families in China, first-generation Chinese immigrant families in the United States, and European American families were asked to recall recent personal events and provide self-descriptions. Euro-American children recalled more specific memory details and described themselves in more personal, as opposed to social, terms than their Chinese and Chinese immigrant peers. Children's self-views mediated the effect of culture on memory details, whereby the self accounted for 50% of variance in the detailedness of memory predicted by culture. Thus, cultural differences in remembering the details of personal experiences are due, at least in part, to cultural views of the self.

Cultural Practices of Memory Sharing

Culture further influences memory development through mnemonic practices. Parent–child memory sharing teaches

children how to represent and reinstate event information in linguistic forms and provides children with the necessary organizational framework around which to structure their autobiographical memories (Nelson and Fivush, 2004; Pillemer and White, 1989). Located in the cultural context, parent–child memory sharing further conveys to children cultural norms and beliefs regarding the purpose and importance of remembering the past and models to children culturally promoted ways of remembering (Wang, 2013; Wang and Ross, 2007).

When conversing with their preschoolers about shared past experiences, Euro-American mothers often use a high-elaborative conversational style in which they dwell on specific episodes, supplement children's responses with rich and embellished information, and provide immediate feedback to scaffold children's participation. In contrast, Chinese mothers often employ a low-elaborate conversational style, where they direct the conversations by frequently posing and repeating factual questions, provide little detail or embellishment to assist the child's participation, and often try to elicit correct answers in a way that emulate a memory test (Wang, 2013; Wang and Ross, 2007). While the high-elaborative conversations between Euro-American mothers and children serve well the purpose of helping children remember details of past events about themselves, the low-elaborative conversations between Chinese mothers and children seem to focus less on memory but reinforce the position of the mother as an authority figure. The use of a high-elaborative style is positively associated with mothers' endorsement of an autonomous self-view and negatively associated with their endorsement of a relational self-view (Wang, 2007).

The thematic content of memory conversations also exhibits marked cultural differences. Euro-American mothers often take a child-centered approach, casting the child as the central character of the story and frequently referring to the child's interests, preferences, opinions, and personal attributes. In contrast, Asian mothers often take a mother-centered, hierarchically organized approach, where they set the direction of the conversation, emphasize social interactions, and frequently refer to moral rules and behavioral expectations with their children (Wang, 2013; Wang and Ross, 2007). The child-centered reminiscing in Euro-American families may encourage remembering self-focused information that highlights one's individuality and uniqueness, and the socially oriented memory sharing in Asian families may facilitate remembering event information related to important others and the community. The following two conversational excerpts illustrate the stylistic and content variations in Euro-American and Chinese mother–child memory conversations (Wang and Fivush, 2005).

American mother–child dyad:

M: … Do you remember doing some crying?
C: Why did I cry?
M: I'm not quite sure why you cried. But do you remember where you were?
C: I cried because I had any, no any balloon.
M: They had no balloon. But then, you were also crying because, did you not want to go home?
C: Yeah.
M: Where were you?
C: At Stewart Park!
M: (Laughs). You did cry a lot at Stewart Park, but, um, this was in Joe's parking lot. Do you remember Joe's Restaurant parking lot? Do you remember standing by the door and crying?
C: Yeah.
M: You do?
C: Yeah.
M: What were you crying about?
C: 'Cause I didn't wanted to leave yet; it was because I wanted to eat.
M: Oh you wanted to eat some more (laughs); is that why?
C: Yeah.
M: Hmm. I remember Mommy tried to pick you up and you put up a little bit of a fight. You were crying real hard. Maybe it was 'cause the balloon and maybe it was 'cause you were hungry. But we knew that you could get another balloon, right?
C: Yep

Chinese mother–child dyad:

M: … Do you remember why Dad spanked you last time?
C: Chess!
M: Why chess? What did you do with chess?
C: Not obedient!
M: How were you not being obedient?
C: (I) threw the pieces on the floor.
M: All over the floor, right? And did you do it on purpose?
C: Umm. I'll be careful next time!
M: Right! That's why Dad spanked your bottom, right? …Did you cry then?
C: (I) cried.
M: Did it hurt?
C: It hurt.
M: It hurt? It doesn't hurt anymore, right?
C: Right. I'll be careful next time.
M: Umm, be careful.

Cultural variations in maternal style of memory conversation have been observed even among Western families. In a study on memory sharing between mothers and their 4-year-old children from Germany, Sweden, and Estonia, Tõugu and colleagues (Tõugu et al., 2011) found that Estonian mothers, who presumably placed less value on autonomy over relatedness, were less elaborative than Swedish and German mothers. Other cultural dimensions may further influence parental conversational styles. For example, Reese and colleagues (Reese et al., 2008) examined mother–child memory conversations in Māori and New Zealand European families. Māori culture traditionally places a strong emphasis on the past and the oral histories of individuals and families. Accordingly, when sharing memories with their preschool and grade-school children, Māori mothers elaborated more in significant past events than did European mothers.

Interestingly, children as young as age 3 years have internalized their mothers' style of conversation when sharing memories about the personal past (Wang, 2007, 2013; Wang and Fivush, 2005). During memory conversations, Euro-American children often contribute more information about the events under discussion and refer more frequently to their own roles, feelings, and thoughts than their Asian peers, who provide less memory information and more often comment on social rules and the roles of others. Furthermore, when

children independently recount their experiences with an interviewer, the volume, style, and content of their memory narratives echo the cultural variations in mother–child memory sharing. Euro-American children tend to provide lengthy, elaborative, self-focused memory narratives and place a great emphasis on personal predilection and autonomy. In comparison, Asian children's memory narratives are often brief, skeletal, relation-oriented, and exhibit a great concern with authority and moral rectitude (Wang, 2004, 2013).

Furthermore, differing parent–child memory sharing has direct consequences for autobiographical memory development. Studies have shown that Euro-American mothers' use of a high-elaborative conversational style early on, compared with Chinese mothers' low-elaborative style, directly facilitates American children's memory recall concurrently and over the long term (Wang, 2007). Maternal style further serves as a potent mediator in explaining cultural differences in children's autobiographical memory (Wang, 2006). Importantly, given the low-elaborative memory sharing early in development within Asian families, Asian children may not develop elaborated narrative schemas for representing and recalling the personal past, which may, in turn, result in less detailed and sparser early childhood memories in adulthood. Indeed, Asian adults exhibit more pervasive and prolonged childhood amnesia than Western adults (Wang, 2003a, 2013).

Culture and Emotion Knowledge

Another important cultural variable that has been investigated in relation to children's developing autobiographical memory concerns cultural beliefs pertaining to emotion. In Western, particularly European American, cultures that emphasize individuality and autonomy, emotion is regarded as a direct expression of the self and an affirmation of the uniqueness of the individual. Explicit expression and communication of emotion is encouraged and considered psychologically beneficial. In contrast, in East Asian cultures that put a premium on social harmony and group interests, such as Korean, Chinese, and Japanese cultures, emotion is often viewed as destructive or even dangerous to ongoing relationships and therefore needs to be strictly controlled. Also, it is believed that emotion should be inferred or implied and explicit communication is discouraged (Markus and Kitayama, 1991; Wang, 2013).

These different cultural beliefs about emotion and emotion communication are reflected in early family socialization. Western middle-class parents are often eager to help children understand and express emotions and feelings in order to raise an 'emotionally intelligent' child. Conversely, Asian parents are not preoccupied with facilitating emotional understanding in their children and emphasize, instead, psychological discipline and behavioral standards (Chao, 1995; Wang, 2013). Moreover, when Euro-American mothers converse with their 3-year-old children about shared emotional experiences, they often engage in extensive discussion of emotion, talking about the causes and consequences of emotions and providing elaborate explanations as to why and how the child was experiencing certain feeling states in the past event. In contrast, Chinese mothers often initiate little discussion about emotion and when they do so, they criticize or comment on the incorrectness of their children's (negative) emotional experience or behavior (Wang, 2013; Wang and Fivush, 2005).

The great emphasis on the personal importance of emotion and emotional understanding and the associated family narrative practices in Euro-American culture directly facilitate children's developing emotion knowledge (Doan and Wang, 2010). When asked to judge the emotional nature of situations in stories or to describe situations likely to provoke various emotions, Euro-American preschoolers outperform their Chinese peers regardless of age (Wang, 2013). For example, in a study with Euro-American and Chinese 3- to 6-year-olds (Wang, 2003b), children were presented with 20 short stories with a protagonist of their age, gender, and ethnicity, and were asked to identify the feeling states of the protagonist by choosing among faces showing happy, sad, scared, or angry emotions. Children's mothers and a second group of adults read the same stories and judged the protagonist's emotions in the same fashion. Based on the concordant judgments between children and adults in each culture, findings showed that American children had a better grasp of emotion knowledge and made more rapid progress in such knowledge than their Chinese peers.

Conceivably, the greater emotion knowledge in Euro-American children helps them better remember autobiographical events for long-term retention. Indeed, compared with their Chinese counterparts, Euro-American children tend to provide more elaborate and detailed memory accounts (Wang, 2004, 2013). The relation of emotion knowledge to autobiographical memory development is directly tested in a longitudinal investigation with European American, Chinese American, and Chinese preschoolers (Wang, 2008). Across the preschool years, Euro-American children showed overall greater understanding of emotion situations and recalled more detailed autobiographical memories than Chinese and Chinese American children. Regardless of culture, children who showed greater understanding of emotion recalled memories with more specific details both concurrently and longitudinally than children who had less emotion knowledge. Emotion knowledge is thus related to autobiographical memory at both the cultural and the individual levels. Furthermore, emotion knowledge functioned as a potent mediator that partially accounted for cultural differences in memory recall.

There are also other cultural factors that may impact on the early autobiographical memory development, such as cultural beliefs concerning the functions or purposes of remembering and sharing personal experiences (Kulkofsky et al., 2009; Wang and Ross, 2007), perceptual styles (Masuda and Nisbett, 2001), language (Wang et al., 2010), prominent lifestyles of a community (Wang, 2003b), and so on. For a comprehensive discussion, see Wang (2013).

Concluding Remarks

The development of autobiographical memory during early childhood exhibits both universality and cultural diversity. It is underlined by general neurological maturation and cognitive and linguistic advances as well as culture-specific beliefs and practices. The end result reflects the interaction between the individual child and the developmental niche embedded in a cultural context.

A functional approach is critical for understanding different modes of autobiographical memory development as the consequence of adaptation to specific cultural settings. We have seen that children's autobiographical memories mirror the conversational styles of their parents and the values and beliefs of their culture. For example, parents who explain the origins and consequences of emotion during memory sharing often have children who have a better understanding of emotion and who recollect emotionally rich memories. Parents who tell personal stories with rich details and elaboration often have children who do the same. Cultures that place value on autonomy and individuality often cultivate children who remember detailed and unique information about their life experiences. Autobiographical memory is evolved as a functional adaptation that supports an individual's ability to navigate in his or her environment and make predictions about the future (Suddendorf and Corballis, 2007). Cultural differences in social and physical environments are bound to produce cultural differences in memory.

Thus, cultural differences in autobiographical memory do not imply any deficit in general cognitive development in one group or another. Instead, the development of autobiographical memory, and social–cognitive skills in general, may reflect specific developmental responses to varying cultural expectations and environmental demands. The general and other-focused autobiographical memory in Asian children, although likely being viewed as unconventional or even deficient in Western cultural contexts, reaffirms a relational self that is privileged in Asian cultures. It further facilitates the development of other social–cognitive skills such as theory of mind (Lu et al., 2008). Detailed remembering of one's own experiences, as much as is taken for granted as a positive personal quality in Western cultures that value independence and autonomy, may signal excessive focus on the psychological self, which is incongruent with the Asian cultural norm that emphasizes relationships.

Ultimately, the development of autobiographical memory is a culturally constructive process. As Bartlett proclaimed 80 years ago (1932, p. 296), "Social organization gives a persistent framework into which all detailed recall must fit, and it very powerfully influences both the manner and the matter of recall."

Automation: Organizational Studies

Federico Butera, University of Milan-Bicocca, Milano, Italy

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Applications and social consequences of automation are explored in factories, offices, travel, banking, retail, safety, and others. Automation is not sheer displacement of tasks from men to machines but a stage in the process toward integrated systems of processes, technology, organization, roles, and values, where technology performs a large variety of existing and new tasks and where interaction is designed among human beings and technical systems.

Technology upsets work but only design resets work. Social and technical methodologies take the opportunity of the always existing 'room of maneuver' for planning, design, and experimentation of systems. Social dimensions in technological development are not effects but instead matter of design.

The Concept of Automation

The word automation, as a contraction of automatic production, was first used in 1952 both by John Diebold – author of the book *Automation: the advent of automatic factory* – and by D.S. Harder, vice-president of manufacturing at Ford Motor Company.

According to Gallino (2006), automation, as a popular term, "indicates different situations where the human physical and intellectual work is replaced by machines and by mechanical, hydraulic, pneumatic, electrical, electronic servomechanisms which may automatically perform sequences of operations."

As a result of 50 years of discussions about a changing phenomena, I define *automation as a stage in the process toward integrated systems of processes, technology, organization, roles and values, where technology performs a large variety of existing and new tasks, and where interaction is designed among human beings and technical systems with the goal to get optimal products and services*.

Three levels of interaction are indicated by most authors: (1) *control systems* based upon closed-loop control mechanism of feedback (on standards) and feed forward (on goals or week signals), performed by any kind of technological device; (2) *integration* of different devices, processes into a unitarian architecture at the level of a factory, firm, network, achieving continuity of processes, and management control; and (3) *system adaptation and innovation*, through rapid detection both of the internal state of the system and of the environment (technical, economic, commercial, etc.). In all cases now those components include tight collaboration among information and communication technologies, advanced managerial systems, and operative work.

Applications and literature indicate that automation is not a device to be purchased, but a dynamic process. In fact (1) different levels of automation depend upon the changing quantity of human tasks embedded in the technical system; (2) different patterns of automation evolve from forms and degrees of interaction between human beings and technology and the way they should co-operate; and (3) systems are not developed once in a time, but along subsequent stages and through change management processes.

Essentials of automation are (1) some necessary human tasks (steering, maintenance, logistics, etc.), because without it there would be only automatic machines; (2) the need for collaboration among human beings and machines, thanks to interrelated activities and interaction through interfaces; and (3) integration of technological, organizational, social system adopted.

The essence of automation is *automatic control*. This concept has been developed as an academic discipline and as a set of technologies applied in a large variety of intelligent human artifacts, that is machines that can read complex data, signals, symbols, have feed-back loop and feed-forward mechanisms, interpret external and internal variables, adjust its conduct accordingly, and that, sometimes, can find new solutions, act without human intervention, and do something which resembles thinking. We live in an environment where most of the artifacts display these features at different degrees: an elevator, a fully automated rolling mill, a remote-controlled automatic train, an auto-piloted aircraft, a personal computer, a robot, and many others. Introduction of automated technologies in various domains can decrease operator workload and increase operator awareness, but researchers have recognized that these technologies must not be developed apart from human operators. As a matter of fact, human-centered automation is an approach to create an environment in which humans and machines work together cooperatively (Billings, 1997; Sheridan and Hennessy, 1984). Principles of human-centered automation constitute, among others, the incorporation of the human operator in the execution of the automated tasks, and appropriate information distribution as well as automated functions that are easy to learn and to operate.

In the following discussion, we will concentrate first upon *industrial automation* and also on an increasing number of applications that go beyond factories.

Applications

Concept, research, and debate on automation have evolved since 1952, according to the available technologies and areas of applications. *Factory automation* came first when mechanical engineering together with production engineering mechanized

 http://dx.doi.org/10.1016/B978-0-08-097086-8.73036-4

both the machine tools and the conveyors in the automobile industry, giving rise to that primitive but seminal type of automation called *Detroit Automation*, that is *transfer lines* where products, e.g., engines, are manufactured and moved without human effort.

In 1913 Henry Ford conducted the first notable material-flow automation exercise by automating the assembly line for automobile engines. Electromechanical engineering developed ingenious devices for automatic control of continuous process industries – as oil, chemical products, cement – and of discontinuous flow process – as steel mills, casting. They were applied also to traffic control of material flows – as in railway's control rooms – and of energy flows – as in power plants. Automation introduced major disruptions in assembly, packaging, and bottling in various manufacturing industries, actually turning from discontinuous processes into continuous ones. In the 1960s, the developments of electronics and computer sciences made those innovations much deeper and wider in all industries. Computer control in the 1970s also extended automatic control into individual operating machines of numerically controlled machines (CNC), advanced robots, integrated CNC, and robots in flexible manufacturing systems (FMS). CNC and FMS were a breakthrough: manufacturing operations were automated and at the same time it was possible to manufacture small batches at costs of economy of scale, since the optimization of planning processes was embedded in the system. In recent cases of automation, processes of R&D, manufacturing, logistics, and distribution were powerful means for integrating among internal and external functions or external units, achieving interfunctional and intercompany seamless processes in the hierarchic-functional classic industrial organizations. Architecture of telecommunications and information systems, and organization network were overboosting those processes and organizational integration.

Human task displacement and production integration pursued two distinct models. The first one was the *unmanned factory* aiming at cutting costs and controversies of the blue-collar workers through advanced mechanization and use of robots, with the aim of getting rid of people, as was in Italy (the Fiat Cassino experiment of the 1980s). The second model was the *integrated factory* which deliberately keeps a meaningful portion of human tasks out of machines, as in the late Toyota developments and in Fiat Melfi. Cost savings and productivity gains are reported in Japanese firms making considerable steps back from full automation. In the *integrated factory*, an optimal distribution of skilled work and automatic control takes place where advantages are not related only to the reduction of direct manpower but also to the integration of various functions and units so as to achieve continuity and flexibility in business processes.

Thanks to industrial robots, new technologies, laser cutting and injection molding, and additive manufacturing machines, production lines can be automated to the point that they can run unsupervised for weeks without any human intervention. But this does not mean that people are not necessary: all these automated machines need someone who services them and tells them what to do. Machine operators become machine minders, with new skills and detailed knowledge about the workplace in general and the production process in particular (Karsvall et al., 2003). This is clear above all in cases where human operators must ensure that the automated system is performing properly and must detect variances, that is undesired status of process or product (Dalmine case in Butera and Thurman, 1984), or situations that diverge from the expected performance (*The Economist*, 2012). Nowadays, clever software, novel materials, more dexterous robots, new processes, three-dimensional printing, and a whole range of web-based services have contributed to the diffusion of a new idea of factory automation beyond production lines: stand-alone machines are linked together into intercompany integrated processes.

A different type of automation is *office automation*. Because of the development of large mainframes, electronic data processing in the 1980s automated large amounts of operations of data collection, retrieval, and processing, both in public and private administrations: the work and the organization in accounting, planning, and control, and commercial departments were deeply affected. Companies introduced a wide range of stand-alone applications, such as manufacturing planning, drafting, and design (computer-aided design – CAD). All external-facing communications and relations at that time were carried out through fax and phone lines. The next stage in information-flow automation, then, were the enterprise resource planning applications, centered on sharing information among multiple individuals and functional areas of a single company. Electronic data exchange (EDI) supported the communication among different departments and different firms.

Video terminals first, then stand-alone personal computers, and finally networked PCs in the 1990s deeply affected the typical clerical and professional operations such as calculating, typing, editing, copying, printing, retrieving, and mailing, introducing a revolution in the office work.

Automation for professionals was intended to substitute and accelerate routine tasks of scientists and professionals. Computer graphics and multimedia at first, and then Internet did not automate tasks, but offered opportunities to *inform* and *communicate* which did not exist before (Zuboff, 1988). In the twenty-first century, some technologies such as VoIP, e-mail, tagging, phone/video-conferencing, and instant messaging built a platform on which users can communicate but can also exchange information, express thoughts, discuss, and reconfigure existing explicit knowledge. This platform is a good example of combining and remixing knowledge in order to produce new knowledge (Haigh, 2006).

Task automation, information technology, and new roles gave rise to the knowledge management approach very popular from the 1990s (Nonaka and Takeuchi, 1995; Brown and Duguid, 1991).

Automation in services is a relatively recent appearance. Automated processes are transforming service delivery in many industries (Karmarkar, 2004). Services are not totally automated; in most cases they are *hybrid services*. They are not simply services in which some of the information are processed digitally. They combine human and machine-based capabilities, depending on human talents to deliver, customize, and personalize (Zysman et al., 2010).

In the *banking sector* it is possible to identify two different automation paradigms. The first paradigm (back-office automation, 1951–80) mainly aimed at enhancing internal

activities. In this context, the database management system can be considered as the first technical device developed for banking purposes (Fincham et al., 1994; Batiz-Lazo et al., 2002). Due to the competitive environment of the 1970s, banks were required to further exploit the benefits of automation and adopted the clearing system (Morris, 1986) and the retail money transfer mechanism (Thompson, 1967; Mandell, 1990). Barclays – the bank that issued the UK's first credit card in 1966 and, a few years later, the first automated teller machines (ATM) – is a typical pioneer of automation (Ackrill and Hannah, 2001; Batiz-Lazo et al., 2002). This kind of automation brings with it certain benefits such as greater storage and faster processing capacity to accommodate the increasing demand for banking transactions.

The second paradigm focused on customer service automation (front-office automation, integrated networking, 1981–to date) and the proliferation of the service delivery channels building on the experience of the ATM. Online customer portals represent an opportunity to involve the front office and the customers more actively in the banking processes, in popular language it is the home banking. Automation improves customer service, by enabling the front office to focus on providing highly personalized services to its customers (Consoli, 2005).

In the *travel industry* the computer reservations system and the airline reservations systems enabled the automation of flight and seat control within an airline. For example, automation allows travel agents not to call the airline to make reservations: therefore, they can save more time to help travelers. Although travel agencies operate most of transactions digitally, there are complex cases and particularly high-value customers that absolutely require human agents. So the travel industry is not completely automated: it is a hybrid service where human beings and technology work together.

In the *retail industry*, bar code devices and RFId allow the sharp reduction of shelf replacement, ordering, cashier work, etc. But, in addition to this, the act of purchasing at a supermarket or at a retailer is no longer just a simple monetary transaction, but a data-generating activity in all respect. At the beginning of the application of ICT to retail, inventories were monitored. Then, information have been run in order to capture consumer preferences and consumption patterns, as well as to manage inventories and supply chains and, sometimes, sold to third parties. As the range of products and services expands and customer demand increases, support systems and technological tools become the integrating factor in business operations. The infrastructure moves the data both to the front office operator and to the marketing operator in charge of customer profiling and segmentation. Web interfaces, multimedia, and tracking tools can manage various interactions and follow up work items connecting front office and service management operations.

In *safety critical domains and sector* such as aviation, air traffic control, and healthcare, automated systems are being used to perform tasks. Automated systems were introduced primarily in order to reduce human error, that until then was thought to be the main cause for most of accidents in safety critical domains (Coyne, 1994; Shappell and Wiegmann, 2000). Automated systems offer several benefits. For example, reliable automation has shown its usefulness in improving conflict detection performance of air traffic controllers (Metzger and Parasuraman, 2005; Sethumadhavan, 2011), in providing faster and accurate decision making in military tasks (Rovira et al., 2007), and in improving pilot performance during icing conditions (Sarter and Schroeder, 2001). In the healthcare industry, automation can help to exchange data and files in different formats between many different departments and partners and to reduce errors. So, automation enables healthcare organizations to streamline operations across departmental boundaries while eliminating human error and delays.

Networking is becoming the normal way of doing: networks of enterprises and networks of people for managing operations, information, or social relations.

A huge amount of functions are run automatically by the internet technology. In addition to the instant and worldwide communication of texts, images, and sound, Internet is going to include functions and structures which in the past were work and organizational systems. The analysis of different service sector suggests that the key source of change is not a complete automation, but a combination between technology and people, since automation is the creation of distributed knowledge among human beings and machines (Bagnara et al., 2010). After all, the role of human operators has become more important in comparison with times in which automation was not part of our lives yet.

Social Effects of Automation

The literature on social effects of automation has had a discontinuous progress. In the late 1950s, developments of automation in various industries gave rise to a wide program of researches on social effects of automation financed by the governments of USA and other industrialized countries. Under unions pressure, these researches came to the worries of an imminent wide diffusion of automation. Advantages commonly attributed to automation included higher production rates and increased productivity, more efficient use of materials, better product quality, improved safety, shorter workweeks for labor, and reduced factory lead times. But the fears of potential consequences in terms of unemployment, deskilling, poor working conditions, work organization, and union/management relations were strong. Automation could also increase the mental workload of an operator if he/she, for example, does not understand how the automated system works or what is being performed. Automation might also decrease an operator's awareness of the situation by alienating him/her from the tasks carried out, leaving the operator less attentive.

Those outstanding researches delineated most of what we know in this field, but in the middle of 1960s they came to a sudden stop when the American 'National Commission for Technology, Automation and Economic Progress' came to the conclusion that employment would not have been affected, due to difficult implementation and limited diffusion of automation in most industries. In the 1970s automation, on the contrary, had a continuous incremental diffusion, without a dramatic drop of employment, but a sharp change in the professional composition of work force, that is less blue collars and more knowledge workers. This phenomenon did not

receive great attention by social scientists, unless in case it appeared relevant for the ongoing studies and criticisms of taylor-fordism. In the 1980s, automation grew at a faster pace and worries returned about employment and working conditions. In the 1990s, discussion and research focused more on information and communication technologies and their impact on the service sector. At the beginning of 2000, a great interest was arising about Internet: in the 2010, automation fell into the larger category of innovation creating economic growth and requiring new skills for new jobs (Cedefop, 2010).

Discussion about the nature and scope of automation may be grouped around two basic divides.

The first great divide was around the issue of *continuity/discontinuity* of technical development. Bright (1958) offers a classification of types of mechanization based upon degree of task allocation among men and machines, including automation. For economists automation is no more than a particular case of technical development and no different social effects should be expected: "the term automation is used in a loose way and there is not any advantage in distinguishing it from advanced forms of technical change" (Buckingham).

Crossman (1960) stated that automation – he was among the first and major scholars – is the second major stage in the displacement of human work substitution of information processing to machines, since in automation "to steer, control, operate a machine, calculate, solve problems, take decision, discussion may be performed by machines as by the human brain." Artificial intelligence made computers more able to cope with complex problems. Development of advanced robotics gave machines sensor-motor skills (Sheridan and Hennessy, 1984).

A breakdown on the contrary was envisaged first by Diebold (1952), who saw automation as a new concept of integrated systems allowing continuous flow in production process. When computers were not yet diffused, Pollock defined automation as "the integration of continuous and discontinuous processes under coordination of electronic systems." In Buckingham's opinion (1961), automation is a new pattern of manufacturing.

According to sociologists as Touraine, Woodward, Blauner, Meissner, and Braverman, automation is a breakdown because massive displacement of skilled and unskilled work into machines overcomes both the craft-based organizations and the mass production model. New tasks, roles, and organizations are created while the amount of work force required for product unit sharply diminishes: most of them agree that human beings maintain mainly control tasks. This happened widely in cases of the last 20 years with *supervisory control* of systems fully controlled by a computer and human beings controlling the computer, ranging from a minimum of switching on/off, to controlling how the computer controls the computer.

Automation, in this prevailing view of social scientists, results to be a breakdown, because it is not only the substitution of any kind of human work, but the generation of new functions not affordable by the human being. Automation, in this view, is the creation of distributed knowledge among human beings and machines that is human–machine cooperation (Bagnara, in Hoc, 2000). *Automation is integration of complex technological and human system by means of automatic devices*. Human work on the other hand does not disappear, but changes its interactional composition. Knowledge workers increase and concentrate on the design, development, and supervision of 'intelligent machines' (Butera et al., 2008).

The second great divide was around the *pessimistic/optimistic view* of automation. The pessimistic view holds that a new type of taylorism is under way, the technological taylorism. The 'intelligence of the system' as a whole would shift upward toward functions which will become more specialized. The results will be a new wave of deskilling among operatives and employees who will become 'transitional ancillary workers' and 'data entry workers.' Consequences of this may be the 'polarization of the labor force,' in the growing divergence between the unskilled masses and a super-skilled elite (Braverman, 1974; Rifkin, 1995).

The opposite view – the optimistic view – sees technology as a way of freeing workers from monotonous or dangerous tasks and from physical fatigue. Machines will do the work and human beings will supervise them (Blauner, 1964). Although the new technologies require less manpower, they should boost the cycle of expansion, giving rise to new firms and new professions (Freeman, 1998).

Researches supported one or another of the mentioned positions and we will shortly refer some of them. It was clear since the beginning that different levels of allocation of tasks to machines affect differently the amount and quality of operative and managerial work (Bright, 1958), with potential *unemployment*.

Authors as Jaffe and Froomkin assumed that the continuity of technical innovation should not generate dramatic changes in the content and amount of *employment*. Rifkin, Forester, and De Masi argued that technological development carries large unemployment. Economists note that job losses are due not only to technological development but in larger proportion to international trade, to business process reengineering, and to reorganization. Evidences are reported that technical innovation creates new jobs and new enterprises with a potential gain in jobs. Sylos Labini (1998) maintains that a national GNP steady growth beyond 3.5% will reduce unemployment also during intense technological innovation.

The impact of automation on the *composition of the workforce* has been studied. Mallet (1975) found that the nature of the productive process, under conditions of semi-automation or automation, is the key for the potential development of technicians as a new working class. Kern and Schumann (1984) corrected the dequalification thesis, but reported about potential polarization of work force. This thesis returns with Rifkin (1995) who charged modern technology with the responsibility of changing human work, by encouraging the coming out of selected group of privileged individuals. Burris (1998) indicates that computerized work generates overall upskilling, some deskilling, and skill bifurcation; Barley and Gideon (2004) and Butera et al. (2008) found that the automation of work gave the starting signal to a real revolution, and from that time on a structural change has occurred in the workforce that can be identified with the development of the knowledge economy, where the actors are knowledge workers. Managers, professionals, and technicians are knowledge workers and their presence rapidly increased in Europe countries from 2000 to 2008. Basically, in countries as Belgium, Netherlands,

Germany, Sweden, Denmark, Finland, Slovenia, Norway, Czech Republic, Austria, United Kingdom, and France today there is not a huge difference in the number of knowledge workers and the rest of the employed population: knowledge workers are 45% of the working force. In other countries as Ireland, Italy, Hungary, Croatia, Greece, and Slovakia, knowledge workers are few, but they increased from 30% (2000) to 40% (2008).

Early researches on *skills* focused first on the change of the nature of tasks in automation. Empirical researches found that manipulation, traditional craft skills, dexterity, and operational ability (Bright, 1958) were fading away. On the contrary, tasks of supervision (Friedman, 1971), 'control skills' (Crossman, 1960), responsibility and relationship with the entire production system (Touraine, 1955), mental or visual jobs (Blauner, 1964), and sophisticated skills to respond to stochastic events (Davis and Taylor, 1976) were increasing.

Undesirable effects and *risks* of automation in dangerous processes have been studied as normal accidents (Perrow, 1984), human and organization errors (Reason, 1990), misinterpretation, and sense making of technological events (Weick, 1990). The Three Mile Island accident in 1979 is a typical example of the way automation can reduce situation awareness, therefore human operator has difficulty in having a proper understanding of the situation so that suitable oversight and interventions can occur.

Most early researches in automated plants found that *job design* criteria moved away from the taylor-fordist tradition, and that new criteria were emerging: interdependence of role and fewer levels of supervision, group behavior, multiskilling and shared responsibility, decline of strict job specifications and close supervision, communication, cooperation and influence, and group autonomy to cope with uncertainties. Recent developments of advanced computers enhance the face-to-face and remote group behavior, the human computer cooperation (Hoc, 2000), and, lately, the human–agent interaction (Lewis, 1998).

Automation changes the entire *role of the human operator* and requires proper knowledge and skills about the workplace in general and the production process in particular (Karsvall et al., 2003). Changes in technology (specifically the introduction of computers and ICT in general) are the main cause of increased demand for skilled workers. Problem solving, reflective skills and metacognitions, communication skills, self-regulations of motivations and affections, interpersonal skills and desire to interact by knowledge workers – but also the ability to use the social capital to fulfill personal desires and organization's needs – are new skills of knowledge workers (Kessels, 2001; Cedefop, 2010).

Conclusions – Effects or Design?

Technology in itself has direct influence on the physical universe of work (light, noise, heat, vibrations, radiation) and the operational universe of work (psychosocial conditions). Design of equipment has a major effect on (1) the amount of work per product unit (work displaced by technology); (2) the operational 'tasks' (man/machine task allocation); and (3) the coordination and control functions left to work system. Technology has only a composite impact with other factors on components of work systems such as roles, organizational structures, communications, work allocation systems and policies, work management systems (such as skills, pay, working hours, regulations), and in particular the cultural and value systems which govern cooperation and conflict (Butera, 1987).

Automation implies more than sheer displacement of operational human tasks because it includes the creation of new tasks of design, maintenance, and coordination, and generates new forms of organization of production and restructuring of the labor market. Automation is at the same time a process of social and technical change, a different distribution of knowledge and operational properties among human beings and technical equipment, and the development of advanced forms of sociotechnical systems in manufacturing and services.

Automation is in essence a sociotechnical system as a combination of business processes, technology, organization, and work according to Trist. Different patterns of supervisory control (Sheridan and Hennessy, 1984), human–computer interaction (Norman and Draper, 1986), and human–computer collaboration (Hoc, 2000) may make a difference in the same level of automation. Participation of stakeholders in the design of the system and of new business along with the process of introduction of the new technology may change the final pattern of sociotechnical systems (Davis and Taylor, 1976).

If technology upsets work, only design resets work. Social and technical methodologies take the opportunity of always existing 'room of maneuver' for planning, design, and experimentation of systems (such as territories, firms, factories, offices, professional units), which jointly may meet economic, social, and technical goals (Butera, 1987). In brief, social dimensions in technological development are not effects but instead matter of design.

Designing integrated architectures of sociotechnical systems, patterns of organization and work, and interaction among human beings and computers is a sociotechnical process and artifact and in principle should be matter of cooperation among different disciplines, as economic technology, organization science, sociology, and psychology. Since automation is matter of design, different practitioners should be involved as engineers, computer scientists, consultants, physicians, and many others. Automation involves different social actors as entrepreneurs, managers, legislators, government, and unions. In a word, development of automation should be a participative event.

Nothing is more matter of joint design of technical, economic, and social systems than the automation as we have represented it. But surprisingly, in the amazing history of automation, the sociotechnical approaches and methodologies have been in most cases excluded. The critical issue is that automation in different applications is mostly viewed as a sheer technological phenomenon. As a consequence, insufficient attention is paid to organizational and human dimensions, whose areas deserve an insignificant proportion of research and investments compared to research and investment on technology. The technological drive is so powerful and dominant that scientists and practitioners in technology are supposed to

be experts also in organization, social systems, roles and professions, and usability and are entitled to design sociotechnical systems, not calling in the research and design of other experts and practitioners.

As a result, a countless series of disasters and social disruptions came along the development of technical development: suboptimizations as the illusion of the unmanned factory, disasters as the Three Mile Island event, social disruptions as the case of Manhattan Highway designed by architect Moses (the omnipotent designer of New York) whose uncontrolled technical innovation transformed the Bronx from a middle-class nice neighborhood in a ghetto as described by Marshall Berman (1982). Berman compares the case of overpowered technologists to the case of the engineer Faust described by Goethe, betting his soul in the belief to be able to design alone a new huge technological settlement: but the resistance to leave their house from an old couple required the help of the devil and the consequent loss of Faust's soul.

On the contrary, many successful positive cases of intentional joint design performed with the cooperation of experts of different technical and social disciplines gave rise to extremely successful results in design of complex systems like civil aviation or healthcare, of products and platforms like Apple or Google, and of composite services like Ikea or Zara.

Automobility

Tim Schwanen, University of Oxford, Oxford, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The term 'automobility' is often used to denote the practices, materialities, institutions, and landscapes centered on the private car. This article introduces recent thinking on automobility in sociology, human geography, political science, and other fields. It describes different conceptualizations of automobility as a system and a regime, reviews studies of how cars are used and experienced by their users, and discusses the future of automobility. It cautions against too much optimism about the imminent demise of automobility but also argues that the possibility of radical change over the next three decades should not be disregarded.

Introduction

The term 'automobility' appears fairly straightforward at first sight, presumably referring to automobiles and movement. Indeed, automobility is often used as shorthand for the practices, materialities, institutions, and landscapes centered on the private car. The term is nonetheless imprecise, and multiple ambiguities can be identified. There is the question whether the prefix 'auto' refer to 'self' as in ancient Greece, or to 'autonomy' as is often argued (Urry, 2004; Paterson, 2007). Likewise, does mobility refer to an artifact that moves, to the human(s) who move(s), or both? The conjunction of 'auto' and 'mobility' multiply ambiguities. If the emphasis is on the artifact and 'auto' refers to self, attention will almost certainly be directed toward self-propelled vehicles like the private car. The combination of artifact and autonomy implies a wider focus – any artifact that affords autonomy in and through movement, including the bicycle, wheelchair, or airplane, is brought into focus. If the emphasis is on the moving human(s), automobility can also refer to walking as both a self-propelled bodily practice and as providing and expressing freedom. Finally, if the emphasis is on both human and artifact, automobility refers to the hybrid ensemble of elements – human bodies/minds, machines, surfaces, signs, values, and so forth – through which movement, and especially autonomous movement, is enacted (Sheller and Urry, 2000).

This last understanding of automobility usefully highlights the complex networks of relations, heterogeneous elements, and practices through which different forms of mobility are brought into being: autonomous mobility is not a simple function of free will – as naïve versions of (neo)liberalism would have it – but a thoroughly relational outcome. This way of thinking also dispels the myth that the machine of the private car is unique in affording autonomy to people. The bicycle, boat, and airplane could, at least in theory, enable similar levels of autonomy. What is unique to the private car is the scale and complexity of the ensembles that make car transport possible, as well as the extent to which (liberal) values like freedom, control, and independence have become inscribed into this artifact. Culture and politics are thus inextricably linked to the car.

Although the concept of automobility is not a priori limited to car-facilitated movement, social scientists have privileged the automobile over other modes of transport in theoretical and empirical researches. This preoccupation reflects not simply that the car is the most widely used form of transport across the global North. It is also because the rise of the car and the ensembles that have made its proliferation possible are as defining for modernity as is urbanization (Sheller and Urry, 2000). Three interrelated concerns in the social science literature about automobility pertain to how hybrid ensembles organized around the private car are best conceptualized, how car-facilitated movement is lived, and how automobile-dominated mobility systems will develop in the future.

System or Regime?

Arguably the most well-known theorization of automobility has been offered by John Urry. Inspired by complexity theory he conceives of automobility as "a self-organizing autopoietic, non-linear system that spreads worldwide" (2004, page 27), comprising a wide range of elements. The car, according to Sheller and Urry (2000), is:

- An object manufactured by one of the most powerful economic sectors within the capitalist system of the twentieth century and from which key concepts for understanding the development of capitalism (e.g., Fordism) have emerged.
- The second largest item of consumption (after housing), which provides status to its owner/user through associated values such as speed, safety, flexibility, freedom, family, and masculinity, and that is a major object of desire, affection, and crime.
- A powerful complex linked to other sectors, such as the oil sector, road construction, hotel sector, car sales/repair, suburban housing, shopping malls, advertising, and urban planning.
- A form of mobility that subordinates other transport modes and determines how, when, and where people engage in activities.
- The dominant culture that feeds into major discourses about well-being and citizenship and provides a rich source of inspiration for literature, film, and other arts.
- A key user of nonrenewable environmental resources and major cause of emissions and pollution.

For Urry the system of automobility is autopoietic because it produces the preconditions of its own expansion. Crucial to how it generates the need for more cars is the ways in which it restructures space–time as part of its development. Consider, for instance, the critical role of the private car in enabling the suburbanization of households, services, and employment, which in many places across the global North has marginalized public transport, walking, and cycling. Consider also how cars have, in Urry's terms, coerced individuals into flexibility: the latter are expected to lead a 'fast,' fragmented, and individualized life in which employment, family life, community participation, leisure, and mobility are seamlessly combined into a do-it-yourself biography.

The system of automobility is nonlinear because small changes can have big effects. One or multiple coincidences in particular places at specific times can set in motion a train of events with profound consequences. In the context of automobility, key coincidences were the activities of early car enthusiasts around 1900, who perfected the then recently invented car by adding lights, electric starters, trunks, and so forth; the victory of a petrol-fueled car over steam and electric alternatives in a horseless carriage competition in Chicago in 1896; and the delivery of the first Ford Model T in 1908 (Urry, 2007). Over time and through autopoiesis, many locales – first in the United States, then in Western Europe and the rest of the global North, and now in the global South – have become locked into automobility: particular technologies (e.g., the internal combustion engine (ICE)), infrastructures (e.g., motorways, gas stations), practices (e.g., driving to work, touring among tourist attractions on holidays), meanings (e.g., driving as freedom), and institutions (e.g., automobile associations, fuel taxes) have become deeply embedded. Some locales – especially in North America – have come to experience 'hyperautomobility,' a situation whereby the distances that individuals travel by car continue to grow when car ownership has reached saturation levels (Freund and Martin, 2009).

Insights from innovation studies align with Urry's ideas. Geels and colleagues (2012) conceptualize automobility as a sociotechnical system – a set of interdependent technologies, infrastructures, markets, user practices, cultural meanings, politics, and technoscientific knowledge. Central to this system is the sociotechnical regime, or the set of rules that orient and coordinate the activities of the social groups that reproduce the sociotechnical system of automobility. Examples of such rules are cognitive routines and shared beliefs, competences, lifestyles, institutions, regulations, and contracts. Innovation scientists like Geels seek to understand the dynamics in automobility and other systems. They hold that sociotechnical systems are relatively stable and due to multiple lock-in mechanisms tend to change only incrementally. Incumbent car manufacturers, for instance, are often hesitant to invest in radical inventions because they may render core competencies and existing production facilities superfluous, demand large sunk investments in new facilities, and may not appeal to potential consumers. This is an important reason why the attempts of EU regulation to stimulate radical innovations in car engines since 1990 have been (mis)used by car manufacturers to stimulate incremental change in ICEs (Dijk and Yarime, 2010). This risk-aversive attitude is reinforced by the practices of banks and other capital investors, and also by governments. While sustainability, and more recently low-carbon mobility, have become important elements in policy discourses across the Western world since 1990, policymakers and politicians are not external to the system or even at its helm: they are often effectively lobbied by the automotive industry; they are reliant on the revenues from fuel, car, and road use taxation; they work with policy instruments that favor incremental over radical change and are dependent on research and expertise that reflects the built-in logic of the existing system; and they are 'acculturated' into status quo forms of knowledge and thinking through training and education.

Radical change in a sociotechnical system like automobility is nonetheless possible. This can occur if and when pressures in the 'sociotechnical landscape' destabilize the regime and 'niche innovations' have built up sufficient momentum to displace or reconfigure the existing sociotechnical regime (Geels et al., 2012). The sociotechnical landscape is the external environment in which a regime is situated and over which regime actors have limited influence; it comprises macrolevel developments in demographics (e.g., population aging across most of the global North), economics (e.g., the rise of neoliberal capitalism), and such processes as anthropogenic climate change. Niches are protected spaces – often market niches or demonstration projects – where inventions are tested and developed and where users have specific demands. In the context of automobility, a range of niches have emerged over the past decades in many cities across the Western world (Geels et al., 2012; see also Nykvist and Whitmarsh, 2008):

- Intermodal travel: initiatives to integrate rail, bus, taxi, car, and walking/cycling – park-and-ride schemes are a well-known example.
- Cultural and sociospatial niches that challenge the normality of automobility through land use (transit-oriented development, compact city) or collective ownership, as with car/bike-sharing programs.
- Mobility management policies by (local) governments, public transport providers, and employers who seek to encourage alternative mobility practices through personalized travel planning, information provision, awareness campaigns, and so forth.
- Public transport innovations through new infrastructure, better information provision, and modernized vehicles – French and Swiss cities (e.g., Strasbourg, Zurich) provide oft-cited examples.
- Information and communication technologies that increase transport's efficiency (as with intelligent transport systems) and substitute for physical movement (as e-commerce does).
- Green propulsion technologies, such as hybrid and battery electric vehicles (BEVs).

The enthusiasm of many activists and scholars notwithstanding, these niches have built up only limited internal momentum to date. They have so far been unable to overhaul the system of automobility built around the ICE, even in countries like the Netherlands or Denmark and cities like London, Zurich, or San Francisco. For Geels and colleagues the regime dominating the system of automobility has become somewhat weaker in countries like the Netherlands and the UK since 1990 – particularly in (the central parts of) cities and among young adults – but is also remarkably resilient. So far

the landscape pressures of climate change, oil scarcity, and the rise of the Internet have been counteracted by such trends as the cultural preference for individual ownership; the cultural valorization of speed and time efficiency; individualization; and the growing markets for conventional cars in emerging countries like China, India, Brazil, Mexico, Nigeria, and Ghana.

The conceptualizations of automobility by Urry and to a lesser extent Geels and colleagues can be, and have been, criticized. They are universalist insofar as they downplay the variations in automobility or rather automobilities. These vary significantly in geographical terms (Edensor, 2004; Merriman, 2009): not only does the power of the automobile lobby differ significantly across Western countries, but landscapes of automobility – road signs, the architecture of petrol stations and roadside buildings, type of cars driven, as well as traffic rules and driving styles – differ markedly across nation-states to such an extent that they contribute to a state's identity. Driving a car along US Route 66 is not quite the same as driving on a German Autobahn or in one of India's many distinctive roadscapes. Another criticism is that system thinking "tends to underplay collective human agency in the production of automobility and to avoid political questions about the shaping of the automobile 'system' " (Böhm et al., 2006, page 5). Rather than being a self-organizing system in a state of lock-in, automobility should be thought of as continually rebuilt through human actions and as profoundly political and suffused with power relations (Goodwin, 2010).

To emphasize both the systemic and political dimensions of automobility, Paterson and colleagues prefer the term 'regime' over 'system' (Böhm et al., 2006; Paterson, 2007), but they use this term in a radically different sense from Geels and colleagues. For Paterson (2007), automobility refers to the cultural, political, and economic institutions, norms, and practices that sustain and promote car-dependent transport and its centrality to global capitalism, environmental degradation, socioeconomic injustice, and the formation of subjectivities – particular ways of being and becoming for human subjects. Böhm et al. (2006) draw on Foucault's philosophy to understand automobility as a regime of truth, power, and subjectivity.

It is a regime of truth because the automobile industry and lobby, car drivers, politicians and policymakers, and scholars tend to position cars as:

- Efficient – their use tends to involve less effort compared to alternative modes of transport.
- Convenient – they enable smooth transfer from A to B whenever and wherever people like.
- Cheap – the costs are, or seem to be, lower than for alternatives.
- Stylish and progressive – they enables users to express and construct certain identities and associate them with modernity.
- Democratic and liberating – they level differences among people and offer freedom and autonomy.

Automobility is also a regime of power as it implies a particular governmentality, or style of governing practices and individuals (Merriman, 2007). A wide range of regulations and institutions have emerged to monitor and discipline drivers and other road users, and to mitigate the negative externalities of car use, such as its environmental degradation, congestion, and traffic accidents. In effect, the rise of automobility has expanded the state's power. Automobility also has geopolitical dimensions. Securing reliable and reasonably cheap access to the oil that keeps cars moving was a significant factor in the decision making of the United States and other Western states that culminated in the Gulf Wars (Goodwin, 2010) and is one reason why the Dutch and UK governments more or less condone Shell's detrimental impact on the environment in the Niger delta and Ogoni livelihoods and quality of life in southeastern Nigeria (Mugveni and Engler, 2011). Yet, the governing of practices and individuals is also undertaken by nonstate actors, and car advertising is key here (Paterson, 2007). In the United States such advertising connected particular car types and brands, such as sports utility vehicles and Hummers, with conquering nature and particular forms of masculinity up to at least the late 2000s. Since then other discourses, which were already prominent in Western Europe, have become more important in US car advertising. These discourses emphasize concern for the environment rather than the conspicuous consumption of resources and have been drawn upon to market smaller city cars and hybrid vehicles, such as the Toyota Prius (Goodwin, 2010).

Because these changes in advertising imply that drivers come to be understood in different ways, they also amount to a shift in automobility as a regime of subjectivity: they assemble possible ways of being for car drivers in new ways. The extent of change should not be exaggerated, however. On the whole automobility continues to position drivers as free and autonomous individuals making their own informed choices. For Böhm et al. (2006), this positioning not only couples automobility to individualism and neoliberalism but also normalizes driving as something that normal people do. In this way, traveling by other means of transport is constructed in some places as a form of deviance. This marginalization of non-car transport is exacerbated by the ways in which automobility's regimes of truth, power, and subjectivity reinforce each other. Through myriad actions of governments, car manufacturers, drivers, and many other agents, the dominance of automobility is continually maintained and reconfigured in ways that are only partially captured by complexity theory with its roots in the natural and exact sciences.

Living Automobility

Thinking about automobility at the macrolevel of systems and regimes is important and useful but also only one side of the coin. It needs to be complemented by, and tied to, micro level analyses of what people actually do with cars – how automobiles are used and experienced and what effects are generated. Studies of car advertisements showing which values and meanings are inscribed into cars are very insightful, but drivers are no passive receptacles slavishly absorbing the messages by car manufacturers, governments, or other stakeholders. Hagman (2010) has shown that whereas understandings of driving pleasure as articulated in Swedish ads and magazines emphasize driving pleasure as inhering in the car and as

a function of its power, speed, and drivability, drivers themselves consider the context of driving – the weather, behavior of other drivers, the destination, and so forth – critically important. This difference seems to reflect that the drivers refer to their everyday experience where the car is a utility and its use tightly regulated, whereas the ads and magazines seek to compensate for triviality of driving and keep alive the ideology of driving as freedom.

The factors that motivate individuals to drive have been studied extensively by transport scholars, psychologists, economists, geographers, and sociologists who have drawn on a wide range of theoretical frameworks, including utility theory, attitude theories, time geography, and theories of social practices. A full review is beyond the scope of this article but available in Lucas et al. (2011). Suffice it to say that, as a result of engineering and economics dominating academic thinking on the topic, research has long privileged instrumental factors in the explanation of why, how, when, and where individuals use cars. Compared to alternative means of transport, cars are preferred, the argument goes, because they waste less time on movement and because they are cheaper, more convenient and comfortable, always and (almost) everywhere available, and safer. More recently, psychologists, geographers, and sociologists have shown that cars have also symbolic and affective values. A number of studies have shown how many suburban mothers use cars to create the (middle-class) identity of a 'good' mother – someone who continually strives to do what is best for her children – for themselves by engaging in particular mothering and mobility practices (e.g., Dowling, 2000). Cars enable those mothers to drive their children to schools, nurseries, and extracurricular activities that need not be the nearest available but instead are the 'best match' with parental aspirations and perceptions about their children's needs. Unlike other transport modes, cars are also believed to be unique means to protect children from traffic injury and 'stranger danger' and to spend quality time with one's children. For many mothers, the car trip is not simply about getting from A to B; it is replete with emotion and meaning and a space–time of care and sociability.

Another social group for whom driving is often more than moving from origin to destination is older adults. Studies from across the Western world – though especially from regions and countries where the marginalization of non-car transport is particularly profound such as the United States and Australia – suggest that older people often experience driving cessation as a loss and a rite of passage into deep old age (Schwanen et al., 2012). For many older adults in the global North, being able to drive in later life is a sign and expression of self-reliance and autonomy, enabling them to avoid the stigmas of dependency and passivity and to enact the neoliberal, ageist ideal of the ageless self.

In short, cars are often more than means for getting around. Apart from being implicated in identity construction, they are sites where drivers undertake activities as diverse as paid work, educating children, and building up social relationships (Laurier et al., 2008), and where distinctive affective bonds are forged between man and machine (Sheller, 2004; Thrift, 2004). Sheller (2004) speaks of "automotive emotions" – visceral and other feelings associated with car use and the embodied dispositions of car users. The idea is that below the threshold of consciousness the interactions between driver, car, and the wider computerized networks in which the latter are increasingly enrolled produce a deep-seated attunement to cars and specific ways of sensing and inhabiting the world. A specific type of cyborg (cybernetic organism) – the driver-car (Dant, 2004) – seems to have come into being, and this human–machine hybrid may be less responsive to policy and other stimuli (pricing, taxation, information campaigns, and so forth) attempting to limit car use than mainstream academic and policy thinking assumes. If this is true, then these affective processes will trap drivers even further in automobility, deepen the marginalization of other forms of transport, and lower the odds that sociotechnical niches other than that of green auto-propulsion technologies will durably reconfigure the system of automobility.

Cars' symbolic importance and automotive emotions may also weaken users' sensitivity to many negative externalities of automobility and the extent to which it puts others at risk. Those others include humans who for some reason (e.g., lack of financial resources, disability, age) are excluded from driving; pedestrians, cyclists, children playing in the street, and others who may be harmed in traffic accidents involving cars; persons with respiratory diseases; people in parts of the world that are of geopolitical importance to the supply of oil; future generations across the world; and many of the forms of nonhuman life inhabiting Earth. There is a degree of multiple deprivation here insofar as households excluded from driving are more likely to live in unhealthier locations where access to non-car modes of transport is poor and traffic safety is low (Martin, 2007). Car use and automotive emotions also put users themselves at risk, by contributing, for example, to sedentary lifestyles.

The Future of Automobility

Given automobility's many 'costs,' it is tempting to predict that automobility must somehow at some point dissolve. The inherent fragility of automobility (Böhm et al., 2006) reinforces this temptation, as a range of contingencies reproduce automobility, including its ability to secure access to oil; to keep congestion, emissions and traffic injury within bounds of acceptability; to perpetuate the idea that cars provide freedom and autonomy to individuals in ways that no other forms of transport can; and so forth. Noteworthy is also that growing numbers of local governments in Europe and the United States have committed themselves to the aforementioned sociotechnical niches and have begun to govern automobility in different ways: plans to construct roads for cars are increasingly shelved and roadspace previously devoted to cars is reallocated to public transport, cycling, and walking.

The temptation becomes even greater when one appreciates that the trend toward 'hyperautomobility' is being eclipsed by the recent phenomena of 'peak travel' (Millard-Ball and Schipper, 2011) and 'peak car use' (Newman and Kenworthy, 2012) – a modest decline, stabilization, and/or slowed-down growth in the demand for car travel at the population level since 1990 or thereabouts in North America, Western Europe, Australia, and Japan. The car continues to be the dominant

mode of transport for daily activities (car use for tourism tends to be excluded in peak travel research!), but among young adults – and especially young men – holding a driver's license, car ownership and the per capita distance by car have been decreasing (Kuhnimhof et al., 2012). Newman and Kenworthy (2012) argue that the reversal of the long-term trend toward growing car use reflects six processes:

- In many countries people now spend so much time in cars that large shares of the population have reached some sort of biologically determined, maximum tolerance level regarding mobility.
- A halting of urban sprawl – the outward growth of urban areas in the form of auto-oriented, low-density, and mono-functional developments.
- A revival of public transport in cities and urban regions.
- Population aging, which means that the share of car commuters in the overall population may be stabilizing.
- Emerging cultures of urbanism, which means that more younger adults remain in the city than previously and perhaps also that more retired households exchange their suburban house for city living.
- The increase in fuel prices, particularly since 2000.

Newman and Kenworthy's list can be challenged. Individual factors may be less or more important in particular localities, and others might be added (e.g., the post-2008 economic downturn, the waning influence of the car industry). There are also broader concerns with peak car thinking. One is the possibility that analysts read too much into 'peak travel' and that growth will pick up in the longer run; another is the narrow focus on the global North. The scale of automobility's expansion is unprecedented in newly industrializing countries (especially China and India) and more recently also in parts of Sub-Saharan Africa. Automobility is now truly globalizing, and it is at the global scale that its system and regimes must be examined and conceptualized. On the other hand, peak car use is a significant phenomenon showing that growth through autopoiesis in the mature systems of automobility of the global North can no longer be taken for granted.

Further to its rapid expansion beyond the Western world, there are other reasons to temper expectations about the imminent dissolution of automobility. Returning to the innovation studies perspective on automobility as a sociotechnical system, we can say that pressures on the regime are increasing but regime actors also adjust to these. Governments and industries have implemented, and keep adopting, a range of measures to mitigate resistance and the negative externalities of widespread car use, but most of these do not profoundly alter the system's basic architecture. Following Unruh (2002), we can say that end-of-pipe solutions and continuity measures tend to be favored. The former treat externalities and are exemplified by catalytic converters and more recently initiatives to increase the fuel economy of conventional vehicles. The latter are incremental innovations and include hybrid and electric vehicles as well as congestion pricing schemes as in London. Such schemes are often positioned as radical innovations – or discontinuity measures (Unruh, 2002) – by transport scholars, but actually curb some of automobility's excesses instead of bringing about its complete dissolution. Potentially discontinuous innovations are sometimes promoted by governments but difficult to implement effectively and often unlikely to result in the creation of true (localized) alternatives to automobility. A case in point is the set of integrated transport and compact city policies that the Dutch National government sought to implement in the late 1980s and 1990s (Schwanen et al., 2004). The growth in car use in the Netherlands may have been tempered to some extent, but other elements of the policy package – most notably a national road pricing scheme – failed to materialize.

Another reason for tempered expectations is that there is no realistic alternative to the ICE-powered car. For Urry (2004, 2011), the lock-in effects of automobility are irreversible, and a successor system will have to offer at least the same level of flexibility in the scheduling and conduct of everyday activities and the same sense autonomy as the private car. Viable regimes of truth, power, and subjectivity may emerge around public transport, cycling, and walking but only in specific pockets within cities. Those regimes cannot be generalized across space as New Urbanists in the United States and compact city adherents in Europe sometimes do. Automobility's spatial legacy in the form of sprawling low-density developments and counterurbanization will necessitate some form of motorized individualized mobility in most locales. At this time the BEV is considered the most likely successor to the conventional car. Yet, even under the most favorable assumptions "BEVs may only provide a niche market over the next 20 years" (Tran et al., 2012, page 332) and major uncertainties about their diffusion remain. Biofuels and other advanced fuels may turn out to be stiff competitors, and large-scale adoption of BEVs may require changes to electricity generation and distribution networks, which may dampen further diffusion. Additionally, "battery storage will need to increase by a factor of four while costs need to drop 70% over the next ten years" (Tran et al., 2012, page 331) for mass diffusion to become a reality. Cultural change is also required: drivers' expectations about how far they can drive without charging need to be lowered and 'range anxiety' – the fear of becoming stranded before the destination is reached – needs to be overcome.

Yet, a glass half full is also a glass half empty. Urry (2011) argues that at some point in the future and in particular places electric vehicles may become fashionable and then 'go viral.' For him, automobility might be profoundly reconfigured if mass diffusion of electric vehicles is entwined with a normalization of carbon budgeting and digital surveillance technologies that allow practically all vehicles and individuals to be traced, trends toward urban compaction and deprivatization, and a weakening of discourses that position mobility as freedom. Perhaps newly industrializing countries like China provide the geographical context where these processes can unfold first given that they are less encumbered by the historical legacy of the ICE than is the global North (Tyfield and Urry, 2012).

It is difficult to predict the future of automobility. Its trajectory may become increasingly geographically differentiated: large differences between the global North and South and within each of these mega-regions can be anticipated. However the system, regimes, and lived experience of automobility may change, there will be winners and losers (Cohen, 2012): the structure of urbanization patterns, the fortunes of firms and lobby organizations, the nature of governmental institutions,

the meanings and emotions associated with mobility, and culturally inflected aspirations of what counts as a good life will change. All of these may induce forms of conflict that merit attention from social scientists.

Autonomous Agents

Tom Bösser, University of Münster, Münster, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Autonomous agents are software programs that respond to states and events in their environment independent from direct instruction by the user or owner of the agent, but acting on behalf and in the interest of the owner. The term agent is not defined precisely, and agent software can range from simple programs composed of a small number of rules to large and complex systems, notably multiagent systems, which comprise many interacting agents. Agent technology was developed in artificial intelligence (AI) research, and can include AI techniques such as learning or reasoning. Agent applications automate aspects of human performance and support the human user by continuous data analysis, monitoring of data streams and large databases, and where routine reactions to events are required. Often these are related to user interaction, technical control systems and electronic trade. Multiagent systems are also used as simulation models for systems with many actors, for example financial markets or traffic. A weak position sees agents as tools that relieve humans from routine tasks suited to computational solutions, while a strong position asserts that agents can be constructed to mimic or even surpass cognitive functions of the human.

What Are Autonomous Agents?

Agents are software programs that:

1. sense events and analyze data streams in their environment,
2. react to certain events and states with defined responses,
3. exhibit goal-oriented behavior representing the intentions of the owner or user of the agent,
4. act proactively on their own initiative, and
5. function in a temporally continuous manner.

Agents may include cognitive functions such as (1) learning, most often adaptation, the simplest form of learning, based on statistical data analysis and observation of process parameters (potentially more complex forms of learning can be included), or (2) communication with other agents or humans, including the exchange of data, parameters, and goal functions.

The autonomy of agents is limited by the interests of the owner. The degree of autonomy ranges from task-specific agents with a restricted domain of application to virus-like entities that proliferate widely and are not under control by their owner, once activated.

Distinction between Robots and Agents

Autonomous agents and robots are closely related: agents are software programs only, whereas robots comprise functions implemented in hardware. Robot behavior is optimized by tuning sensors, effectors, and the control program; agents are composed of software functions for data analysis and communication, and a control program. Robot behavior must also be optimized with regard to energy and physical performance parameters, which are less important for agents. There is a tendency to use the terms software robot and agent synonymously.

Agents are distinct from software programs in general by their continuous operation, their reactive behavior, and their (partial) autonomy. It should be noted that feedback control systems also have some of these properties but are generally associated with the monitoring of continuous variables and the control of set points or simple forcing functions (e.g., the thermostat).

Constructing Agents

Agents are specific to their tasks and their environment. The design of a specific agent is optimized for its application to maximize performance and reliability, and to minimize error probability, cost, and other relevant properties. For a well-understood task in a predictable context, agent software can be specified as a discrete control system or a state machine. Autonomous agents are expected to be 'intelligent.' Intelligence refers to the extent to which the agent responds in an optimal manner to the events that it monitors, in terms of correctness, speed, and reliability of responses. The goal of an agent is to optimize the benefit for the owner of the agent. It is thus important to note that it is the behavior only that is judged to be intelligent, not whether the underlying computational processes are implemented as a fixed control algorithm, or include planning, learning, and reasoning (McFarland and Bösser, 1993).

Design Principles for Agents

Design principles that can be applied to agents are:

1. Development of a reactive system based on profound analysis and understanding of the tasks and context in which the agent is operating. An agent of this type may be implemented as a limited number of rules, or a state machine. The intelligent behavior is not a function of the real-time computations of the agent, but of the optimal selection of a limited number of rules or behaviors that overall generate successful behavior.
2. Artificial intelligence (AI) principles, including planning and learning, can be used to make an agent adaptive and react successfully in many different states that need not be anticipated in the design phase.

3. Agents often are designed according to inspirations and partial structural analogy to biological and social systems, with features defined in anthropomorphic terms such as mood and emotions. Generally the definitions in anthropomorphic terms are aspirations to realize a certain functionality rather than the claim to reproduce biological or even human capabilities.

Implementation of Agents
